Editor's Introduction

THE *History of Economic Analysis,* upon which Joseph A. Schumpeter worked during the last nine years of his life and which he had not quite finished, was the result of his intention to translate, revise, and bring up to date the 'little sketch of doctrines and methods' (*Epochen der Dogmen- und Methodengeschichte*) written for the first volume of Max Weber's *Grundriss,* which was published in 1914.[1] This was a long essay (about 60,000 words) of a little more than a hundred pages which was divided into four parts or chapters. An examination of the table of contents will show that these four parts or chapters cover very briefly the same general topics that are treated in much more detail in Parts II, III, and IV of the 1200-page *History of Economic Analysis.* The first two, which are concerned with (1) the development of economics from the work of the philosophers and the popular discussion and (2) the discoveries in economics associated with the physiocrats, Turgot, and Adam Smith, are discussed in a single part in the present work (Part II: From the Beginnings to 1790). The third and fourth divisions in the two works are roughly parallel. The four main headings in the *Epochen* were as follows:

I. Die Entwicklung der Sozialökonomik zur Wissenschaft (The Development of Economics as a Science).
II. Die Entdeckung des wirtschaftlichen Kreislaufs (The Discovery of the Circular Flow of Economic Life).
III. Das klassische System und seine Ausläufer (The Classical System and its Offshoots).
IV. Die historische Schule und die Grenznutzentheorie (The Historical School and the Marginal Utility Theory).

The old essay had been out of print; it had never been translated from German into English; many people had been interested in it and had urged a translation. After herculean labor, J. A. S. had finished his monumental *Business Cycles* in 1938 and sought relaxation in *Capitalism, Socialism, and Democracy,* which he regarded as distinctly a 'popular' offering that he expected to finish in a few months. He completed it some time in 1941. In the meantime he began to give a half course in the History of Economic Thought at Harvard. He gave this course for the first time in the fall term, 1939 and for the last time in the spring term, 1948—giving it in every year except in

---

[1] *Grundriss der Sozialökonomik,* I. Abteilung, *Wirtschaft und Wirtschaftswissenschaft,* pp. 19-124, published by J. C. B. Mohr (Paul Siebeck), Tübingen, 1914; 2nd ed. 1924.

1940 when he was on leave. This last development was probably the decisive factor. He was once more teaching in a field which had always interested him. It was natural to think of writing in that field. He would translate, revise, and bring up to date the *Epochen*. In the beginning he did not stress so much the purely analytic element in the writings of the economists discussed in his course and about whom he wrote. In fact, for a long time I had the impression that he was writing a history of economic thought.

His original plan was not a very ambitious one. He certainly had no intention of spending nine or ten years on a history of economic analysis. At first he probably thought of giving his spare time for a few months or a year to a little book of three or four hundred pages. Later he thought of one large volume of six or seven hundred pages. His main interest was his work on theory and he planned to write his major contribution in this field. He worked constantly at his mathematics because he believed it to be an indispensable tool of modern theory. He envisaged a theory which might some day synthesize dynamic economics in the same way that the Walrasian system summed up static economics. Eventually he modified this program to the extent that he would first write a little Introduction to Theory which would be for this kind of theory what the *General Theory of Employment, Interest, and Money* was for Keynesian theory. He read the current theoretical literature (largely in periodicals), worked at his mathematics, and assembled voluminous notes. The results of this work are reflected in some of the later parts of the *History*, especially in those parts which sum up modern developments.

It is hard to say just why his work on the *History* constantly became more and more elaborate and took up more and more of his time. It was partly because his interests were constantly broadening, and he found it increasingly difficult to treat very briefly something which was to him a fascinating development. (For example, the scholastics and the philosophers of natural law became an absorbing interest in the early forties.) Here also he could weave together the threads of all his interests—philosophy, sociology, history, theory, and such applied fields in economics as money, cycles, public finance, socialism. I believe also that the war had something to do with it. I remember his telling one or two friends that he found work on the *History* a rather soothing occupation for wartime. It removed him temporarily from a grim reality which grieved him beyond measure because he was convinced it would destroy the civilization he loved.

As always he wrote out everything in his own hand and kept everything that he wrote. It is possible to see, therefore, how the early treatments became more and more elaborate. He probably began writing the *History* in 1941. During the years 1942 and 1943 he seems to have had typed a good many chapters and sections, most of which were subsequently revised. The only substantial parts of the *History* written in the early years which were not later rewritten are the chapter The 'Mercantilist' Literature, which was typed in June 1943, the chapter on Sozialpolitik and the Historical Method, part of which was typed in January 1943 and the rest in December 1943, and the section on Senior's Four Postulates at the beginning of Chapter 6 of Part III (General

Economics: Pure Theory). These, too, would probably have been revised or rewritten had J. A. S. lived to complete the *History*. Occasionally a few pages of an earlier version were incorporated in later versions. This process is described in some detail in the Appendix.

As time went on, he began to emphasize that this was a history of economic analysis and not a history of economic thought. He makes this clear in a brief description which he wrote early in 1949 for his English publishers, Allen & Unwin, in which he stated:

> This book will describe the development and the fortunes of scientific analysis in the field of economics, from Graeco-Roman times to the present, in the appropriate setting of social and political history and with some attention to the developments in other social sciences and also in philosophy. The ideas on economic policy that float in the public mind or may be attributed to legislators and administrators, whether or not embodied in elaborate systems, such as liberalism or solidarism and the like, which are commonly referred to as economic thought, come in only as part of that setting. The subject of the book is the history of the efforts to describe and explain economic facts and to provide the tools for doing so.
>
> Since the very possibility of treating the history of economics like the history of any other science is controversial, Part I of the book is devoted entirely to the methodological questions that this approach raises and especially to the question how far the distinction between scientific economic analysis and economic thought is valid in spite of the interaction between the two. Part II then tells the story of the growth of historical, statistical, and theoretical knowledge of economic phenomena from its beginnings in ancient Greece to the emergence of economics as a recognized special field and to the consequent appearance in the second half of the eighteenth century of systematic treatises, of which A. Smith's *Wealth of Nations* proved to be the most successful one.
>
> Part III covers the period between 1776 [later changed to 1790] and 1870, and Part IV the period between 1870 and 1914. Part V is to help the reader to relate the present state of economics to the work of the past. Throughout, an effort has been made to make the most important contour lines stand out without sacrificing correctness to simplicity of exposition.

I stated at the beginning that J. A. S. had been working on his *History of Economic Analysis* during the last nine years of his life. In a larger sense, he had been working on it all his life. Probably all of his writing and all of his teaching contributed to the final result. The lecture which he gave on leaving Czernowitz in 1911, for example, was entitled 'Vergangenheit und Zukunft der Sozialwissenschaften.' [2] This was a brief outline of what first became the

---

[2] 'The Past and Future of the Social Sciences.' A revised and enlarged version was published by Duncker & Humblot (1915) in the *Schriften des Sozialwissenschaftlichen Akademischen Vereins in Czernowitz.*

Epochen and finally the *History of Economic Analysis*. His Presidential Address before the American Economic Association in December 1948—'Science and Ideology'—was concerned with some of these problems of methodology which he takes up in Part I of the *History*. The course which he gave at Harvard on the History of Economic Thought covered essentially the period between A. Smith and A. Marshall, with special emphasis on the Ricardian system of economic theory. In the course on Advanced Economic Theory[3] he discussed many of the problems which are written about in Part IV, Chapter 7 (Equilibrium Analysis) and in Part V. He also taught at Harvard a course on Socialism and sometimes a course on Business Cycles and the course on Money. At the University of Bonn, J. A. S. held the Chair of Public Finance, but also conducted a seminar which was concerned largely with theory, including the theory of money, and with epistemology. While at Yale for a year, he taught the course in International Trade. Not only his courses, but also his many articles on almost every aspect of economics, his numerous book reviews, his biographical essays, his books—all were part of the preparation for writing the *History of Economic Analysis*. Even his reading for pleasure and recreation—he loved to read biographies, preferably those in many volumes—contributed to that fascinating knowledge of men, events, and backgrounds which is apparent throughout the *History* and which will liven for some readers sober discussions on fine points of economic analysis.

No part of the manuscript was in final form but some parts were more nearly complete than others. The three main Parts (II, III, and IV) were practically finished, with the exceptions noted in the Appendix; the introductory Part I and the concluding Part V were being written at the very end. The last thing written, at the close of 1949, was apparently the chapter on Keynes and Modern Macroeconomics at the end of Part V. This was left behind to be typed when he went to Taconic for Christmas and to New York for the meetings of the American Economic Association. On his return from the meetings, he started to write up his address, 'The March into Socialism,' and also to read the typescript of Part III of the *History*. He left several pages of notes for revisions in the first three or four chapters in this part on 'classical' economics. His death on January 8, 1950, made it impossible for him ever to carry out these revisions.

The entire *History* was first written in longhand. Some portions, such as the early chapter on Money (Part II, ch. 6) and much of the material on the

---

[3] At the beginning of the reading list for this course (Economics 203a) in the fall term of 1948-9 occurs the following brief description:

> The primary object of this course is to train the students in the art of conceptualizing the salient features of the economic process. But discussion of individual problems will give the opportunity of rehearsing critically large parts of traditional theory, old and new. The program for this term includes, first, a preliminary survey of certain fundamental notions, especially determinateness and stability; second, the general dynamics of economic aggregates; third, the general theory of the behavior of households and firms. Though some knowledge of the calculus and of differential equations is desirable, purely mathematical aspects will not be stressed.

Walrasian system of equilibrium (Part IV, ch. 7, sec. 7), existed only in longhand and had never been typed. In a few cases there were even several alternative versions in longhand. Other portions had been typed but not read by the author after typing. Still others had been read in typescript and corrected in pencil with notes and questions for subsequent revision. There were occasional references to be filled in, and J. A. S. told me that the references needed to be checked. I was to have helped at this task. The interested professional reader will find more detailed information on these points in editorial notes throughout the work and in the Editor's Appendix.

J. A. S. had no regular secretarial assistance during most of the period when he worked on this book, but he did have people who knew his handwriting and who typed for him. Occasionally he sent off a large batch of completed manuscripts to be typed. He wrote most of his letters in his own hand. This, of course, added immensely to the burden of his work and meant that his material was never filed as an efficient secretary might have filed it. He did not acquire a part-time secretary until the summer of 1948, when he was president of the American Economic Association and simultaneously carrying on all his other work. Even then he was reluctant to take the time to instruct her properly because the days and weeks were never long enough to do all the things he planned to do—his teaching, his consultations, his reading, his writing, his correspondence.

I conceived my editorial task to be the simple one of presenting as complete and accurate a version of what J. A. S. actually wrote as possible but not to attempt to complete what he had not written. No outline of the whole work existed, and I had read none of it before his death because J. A. S. wished me to begin with the introduction, upon which he was working, and to read the whole work in its proper order. The material was found in many places—some of it in file boxes, some of it piled on shelves—in the Cambridge study on Acacia Street, in the Taconic study, and a little of it in his office at Littauer Center. It took me two or three months to discover that the *History* was nearly completed, and sections or subsections kept turning up for some time. The initial fitting together of the pieces was made difficult by the fact that the manuscript pages were often not numbered at all, and that the typescript was not numbered consecutively from the beginning but only in small batches as typed. J. A. S. used only the first typescript for the publisher. He never bothered with a carbon copy for himself. Fortunately the various people who typed the manuscript kept a carbon copy, and these carbon copies were stacked in a room on the third floor of the Acacia Street house. Some of these—those done in 1943 and 1944 especially—were dated. I kept looking until I found manuscript and a first typescript to match the carbons. In a number of cases, the carbons represented early treatments subsequently discarded or partially incorporated in later versions. As I read the whole work over and over again I found that, though no outline or table of contents had been written out, such an outline existed within the text. There was a minor complication due to the fact that the number of chapters originally planned was reduced from eight to seven in the case of Part II and from ten to eight in the case of

Part IV. In the end, however, I had almost no difficulty in determining where each section or subsection belonged or in deciding which was the latest of two or more versions. These problems are discussed in the Appendix.

The task was immensely complicated by the length of the book. Even though I am an economist with some editorial experience, it was not easy to put together so long a work dealing with so many economists, writing in so many languages over so long a period. In general, the procedure was as follows: the sections still in manuscript were typed; then various assistants read the manuscript to me from beginning to end while I corrected the typescript; references were completed and checked; titles and subtitles were supplied where necessary; after the Oxford University Press edited the typescript, I went through it once more to pass on the changes made, to supply cross references to other parts of the work, to check against a card catalogue of authors; finally various assistants read the author's copy to me from beginning to end while I corrected the galley proofs. During each successive reading of the *History*, more and more minor inaccuracies and uncertainties were cleared up. Doubtless this process could have gone on indefinitely, but considerations of time imposed a reasonable stopping place. It seems appropriate at this point to acknowledge gratefully a gift from David Rockefeller and a grant from the Rockefeller Foundation which made possible much of the secretarial and editorial assistance outlined above.

One difficulty should perhaps be touched upon here. It applies especially to the unfinished portions of the *History*. J. A. S. often started and abandoned many treatments of the same subject. He kept all these trial efforts and his original notes together with the finished bits of manuscript so that it was not always easy to know what was a more or less final version. Sometimes the date of a reference or the incorporation of a page or two of an earlier version was a clue. Another difficulty is that his plans or his notes for revision were often in a mixture of English, German, and shorthand. Four pages of such notes are reproduced in the Appendix (the plan and the final page for the money chapter in Part II and two outlines for Part V). I made no effort to interpret or carry into effect either such shorthand revisions or brief suggestions as to revisions. I merely incorporated the straightforward corrections on the first typescript. The original manuscript, the alternative versions, the notes, and the first typescript with corrections and suggested revisions in the hand of J. A. S. will all be deposited in the Houghton Library at Harvard University, where they may be consulted by the interested scholar.

Material has been added by the editor only for clarity or consistency, and such additions are enclosed in square brackets. This applies especially to titles and subtitles, editorial notes in the text, and editorial footnotes. In the beginning, J. A. S. merely numbered his sections. As time went on, he added titles for both sections and subsections. Occasionally he left a blank where he had not made a final decision. The titles supplied by the editor were based on the text and are all enclosed in square brackets. There are both author's comments and editor's notes in square brackets, but it is almost always possible to distinguish between them. The author's comments are usually in the midst of quotations, whereas the editor's material occurs as complete sentences at the end of notes, as complete footnotes, or as a complete paragraph in the text printed in the footnote type. Where there is danger of confusion, the initials 'J. A. S.' or the abbreviation 'Ed.' are used.

There are some repetitions, of which J. A. S. was well aware, and some omissions of material promised 'above' or 'below.' For the most part, I did not attempt to eliminate repetitions except such as were very close together and obvious. When the same article was quoted several times in different connections or the same idea expressed several times in different parts of the text, I did not feel competent to remove some references and leave others, although the author himself would have done so. I have attempted to call attention in footnotes to the more important omissions, which were the consequence of some parts of the work being not quite complete. At the suggestion of Richard M. Goodwin, I also called attention in footnotes to some of the other writings of the author which had a bearing on problems under discussion, since J. A. S. hardly ever referred to his own work either in his teaching or in his writing. Other people could doubtless have done this better but no one else had the time to go through this long work again and again.

Occasionally it was impossible to read a word or a word was omitted or a sentence was incomplete. I dealt with such problems to the best of my ability. The vocabulary used was extensive and many an unusual English word had to be tracked down in the great Oxford Dictionary. Many of the foreign titles quoted were not to be found in any of the Harvard Libraries, nor were they listed by the Library of Congress. By using various foreign book lists and with the help of scholars in this country and in Europe, I was able eventually to verify almost all the authors and titles.

For the most part, J. A. S. was specific about the editions used where this was important, but occasionally there was a little difficulty in this connection, because the author had worked in so many places over such a long period that inevitably he had used different editions and printings of the works quoted. He undoubtedly used European university libraries and his own extensive library for his notes and writings before he came to Harvard in 1932. At that time his library was packed up and stored in Jülich near Bonn. It was not brought to the United States before the war because at first he did not have room for it and later there were various 'practical difficulties' (perhaps more imaginary than real). Then came the war. Eventually it was destroyed in the bombing of Jülich by the American Air Force. Only about a hundred books (mostly English biographies) were salvaged from the rubble. After 1932, J. A. S. used working books acquired in this country and my library of economics books in Taconic. He spent much time during the war working quietly in the Kress Library of Business and Economics at the Harvard School of Business Administration. (He also read extensively in the professional periodical literature, and he read the current books and reprints in many languages which scholars everywhere sent him.) This may help to explain why both earlier and later editions of the same work are listed in the *History* and why I found page references to two different English translations of Volume I of *Das Kapital* and to both English and American editions of Cairnes (*Some Leading Principles*) and Keynes (*Tract on Monetary Reform*). The original work on Turgot's *Réflexions* was obviously done before the publication of the Schelle edition.

There is no attempt to present a bibliography with this *History of Economic Analysis*. In a sense the whole history may be regarded as a bibliography. I do, however, present a list of books frequently quoted where the edition used is important and where this is not specifically mentioned on each occasion. J. A. S. used the fourth edition of Marshall's *Principles* (1898) because both he and I owned this edition. (He had many qualms about this and wondered if he shouldn't shift to a later edition.) This list of books (with the edition or printing used) is to be found at the end of the work, following directly after the Appendix.

The reader may be puzzled by the significance of the indented material which occurs in the first 566 pages of this work. It must be admitted at once that this is an error, the consequence of a misunderstanding between the printer and publisher on the one hand and the editor on the other. All the indented material should have been set in footnote type (not indented) as being supposedly of lesser interest to the average reader. It will be recalled that J. A. S. was attempting to write a history which could be published in one volume of possibly six or seven hundred pages. As time went on, however, his treatment became more and more elaborate, and he was aware of the fact that the book was getting too long—also that he was treating subjects which might not interest the average reader. He therefore decided to write the book on two levels, with the more or less technical material, the epistemological and philosophical discussions, and the biographical sketches set in small type so that they would take up less space and so that they could be easily skipped. He indicated this by having them typed in single space like the footnotes. The printer, having chosen an appropriate type for the book, decided that there would be too much of the small or footnote type and evolved the plan of putting this 'secondary' material in the text type but indented, thus reversing what the author had intended to be the relative importance of this material. Unfortunately this plan was not made clear to me and nearly half the *History* was in galleys before I saw any proof. Resetting all this would have involved both considerable expense and considerable delay. I therefore let it stand for the most part and had only small sections of incomplete or very technical discussion reset in small type. A glance at pages 414-18, 449-52, and 464-9, where Comte, Mill's *Logic*, and Longfield, Thünen, and John Rae are discussed, will illustrate the kind of material which the author intended to have subordinated. I am not sure that he was always right in his emphasis, especially with reference to the biographical sketches, which appeal to most people who have read them.

In the rest of the *History* (the last two chapters of Part III and Parts IV and V), I divided the 'secondary' material between the text type and the footnote type, with only two or three 'philosophical' discussions indented as had been done earlier. The biographical sketches, some of which were rather long, were almost all printed in the larger rather than in the smaller type, as originally intended. I did this because I was persuaded that it would be difficult to read so much material in the very small footnote type already chosen, although this change was, of course, contrary to my policy of publishing the *History* as nearly as possible as J. A. S. had written it. The manuscript and first typescript deposited in the Houghton Library will show what the author planned in this respect.

It is possible for me to mention here only a very small number of the people without whose advice or assistance I could not have prepared the work for publication. Arthur W. Marget was the first person to read the entire *History* in typescript, to advise me about the unfinished sections, and to discuss general editorial policy with me. He also put together and edited the chapter on Value and Money in Part II. This chapter had never been typed, the manuscript pages had not been numbered, and there was some uncertainty about the order of the pages in a few cases. Gottfried von Haberler also read most of the typescript and helped me check obscure references and any theoretical points which troubled me. Paul M. Sweezy read all of the proof, made many valuable suggestions, and caught several errors which had escaped me. Richard M. Goodwin first put together for me the material in Part IV, Chapter 7, and Part V, which were unfinished and upon which J. A. S. was working at the time of his death. This was the important material upon equilibrium analysis and upon modern developments. Alfred H. Conrad read some of the typescript and much of the proof and checked mathematical formulations. William J. Fellner read some of the typescript, and Alexander Gerschenkron read some of the proof. Frieda S. Ullian was both resourceful and indefatigable in tracking down obscure authors. Anna Thorpe has helped at every stage of this book from typing some of the early manuscript many years ago to helping me read proof and prepare an index. Her familiarity with J. A. S.'s somewhat difficult handwriting and his methods of work helped solve many a problem. My gratitude goes out to these people and to all the others who helped me in one way or another to edit this *History of Economic Analysis*.

ELIZABETH BOODY SCHUMPETER

Taconic, Connecticut
July 1952

NOTE: After Professor Schumpeter's death and up to the last weeks of her prolonged illness, Mrs. Schumpeter devoted most of her time to preparing this book for publication. At her death the author index was nearly finished, but the work on the subject index had been barely started. Dr. Robert Kuenne undertook the difficult and extensive task of preparing the subject index; he also completed the author index and co-ordinated the two.

The publishers are deeply grateful to Professor Wassily Leontief for his help in making publication possible.

Table of Contents

EDITOR'S INTRODUCTION v

PART I

INTRODUCTION

SCOPE AND METHOD

CHAPTER 1 INTRODUCTION AND PLAN 3

1. Plan of the Book, 3
2. Why Do We Study the History of Economics?, 4
3. But Is Economics a Science?, 6

CHAPTER 2 INTERLUDE I: THE TECHNIQUES OF ECONOMIC ANALYSIS 12

1. Economic History, 12
2. Statistics, 13
3. 'Theory,' 14
4. Economic Sociology, 20
5. Political Economy, 21
6. Applied Fields, 22

CHAPTER 3 INTERLUDE II: CONTEMPORANEOUS DEVELOPMENTS IN OTHER SCIENCES 25

1. Economics and Sociology, 25
2. Logic and Psychology, 27
3. Economics and Philosophy, 28

CHAPTER 4 THE SOCIOLOGY OF ECONOMICS 33

1. Is the History of Economics a History of Ideologies?, 34
    - (a) Special Nature of 'Economic Laws,' 34
    - (b) The Marxian Exposition of Ideological Bias, 35
    - (c) How Does a History of Economic Analysis Differ from a History of Systems of Political Economy; from a History of Economic Thought?, 38
    - (d) The Scientific Process: Vision and Rules of Procedure, 41

PART II

FROM THE BEGINNINGS TO THE FIRST CLASSICAL SITUATION

(TO ABOUT 1790)

CHAPTER 1 GRAECO ROMAN ECONOMICS 51

1. Plan of the Part, 51
2. From the Beginnings to Plato, 53

3. Aristotle's Analytic Performance, 57
4. On the Origin of the State, Private Property, and Slavery, 59
5. Aristotle's 'Pure' Economics, 60
    (a) Value, 60
    (b) Money, 62
    (c) Interest, 64
6. Greek Philosophy, 65
7. The Contribution of the Romans, 66
    (a) Absence of Analytic Work, 67
    (b) Importance of Roman Law, 67
    (c) Writings on Agriculture, 70
8. Early Christian Thought, 71

CHAPTER 2 THE SCHOLASTIC DOCTORS AND THE PHILOSOPHERS OF NATURAL LAW 73
1. The Great Gap, 73
2. Feudalism and Scholasticism, 74
3. Scholasticism and Capitalism, 78
4. Scholastic Sociology and Economics, 82
    (a) From the Ninth Century to the End of the Twelfth, 83
    (b) The Thirteenth Century, 87
    (c) From the Fourteenth Century to the Seventeenth, 94
5. The Concept of Natural Law, 107
    (a) The Ethico-Legal Concept, 108
    (b) The Analytic Concept, 110
    (c) Natural Law and Sociological Rationalism, 113
6. The Philosophers of Natural Law: Natural-Law Analysis in the Seventeenth Century, 115
    (a) The Protestant or Laical Scholastics, 116
    (b) Mathematics and Physics, 118
    (c) Economic and Political Sociology, 119
    (d) Contribution to Economics, 122
7. The Philosophers of Natural Law: Natural-Law Analysis in the Eighteenth Century and After, 122
    (a) The Science of Human Nature: Psychologism, 123
    (b) Analytic Aesthetics and Ethics, 126
    (c) Self-Interest, the Common Good, and Utilitarianism, 130
    (d) Historical Sociology, 134
    (e) The Encyclopédistes, 137
    (f) The Semi-Socialist Writers, 139
    (g) Moral Philosophy, 141

CHAPTER 3 THE CONSULTANT ADMINISTRATORS AND THE PAMPHLETEERS 143
1. More Facts from Social History, 143
    (a) Incidental Factors in the Emergence of the National States, 144
    (b) Why the National States Were Aggressive, 146
    (c) Influence of Special Circumstances on the Contemporary Literature, 148
2. The Economic Literature of the Period, 155
    (a) The Material Excluded, 156

    - (b) The Consultant Administrators, 159
    - (c) The Pamphleteers, 160
  - 3. Sixteenth-Century Systems, 161
    - (a) The Work of Carafa, 162
    - (b) Representative Performances: Bodin and Botero, 164
    - (c) Spain and England, 165
  - 4. The Systems, 1600-1776, 167
    - (a) Representatives of the Earlier Stages, 167
    - (b) Justi: the Welfare State, 170
    - (c) France and England, 174
    - (d) High Level of the Italian Contribution, 176
    - (e) Adam Smith and the *Wealth of Nations*, 181
  - 5. Quasi-Systems, 194
  - 6. Public Finance Once More, 199
  - 7. Note on Utopias, 206

CHAPTER 4 THE ECONOMETRICIANS AND TURGOT 209

  - 1. Political Arithmetick, 209
  - 2. Boisguillebert and Cantillon, 215
  - 3. The Physiocrats, 223
    - (a) Quesnay and the Disciples, 223
    - (b) Natural Law, Agriculture, Laissez-Faire, and l'Impôt Unique, 228
    - (c) Quesnay's Economic Analysis, 232
    - (d) The Tableau Économique, 239
  - 4. Turgot, 243

CHAPTER 5 POPULATION, RETURNS, WAGES, AND EMPLOYMENT 250

  - 1. The Principle of Population, 250
    - (a) The Populationist Attitude, 251
    - (b) Growth of Factual Knowledge, 253
    - (c) Emergence of the 'Malthusian' Principle, 254
  - 2. Increasing and Decreasing Returns and the Theory of Rent, 258
    - (a) Increasing Returns, 258
    - (b) Decreasing Returns: Steuart and Turgot, 259
    - (c) Historical Increasing Returns, 262
    - (d) Rent of Land, 263
  - 3. Wages, 266
  - 4. Unemployment and the 'State of the Poor,' 270

CHAPTER 6 VALUE AND MONEY 276

  - 1. Real Analysis and Monetary Analysis, 276
    - (a) Relation of Monetary Analysis to Aggregative or Macroanalysis, 278
    - (b) Monetary Analysis and Views on Spending and Saving, 280
    - (c) Interlude of Monetary Analysis (1600-1760): Becher, Boisguillebert, and Quesnay, 283
    - (d) Dearness and Plenty versus Cheapness and Plenty, 285
  - 2. Fundamentals, 288
    - (a) Metallism and Cartalism: Theoretical and Practical, 288

    - (b) Theoretical Metallism in the Seventeenth and Eighteenth Centuries, 289
    - (c) Survival of the Antimetallist Tradition, 293
- 3. Digression on Value, 300
    - (a) The Paradox of Value: Galiani, 300
    - (b) Bernoulli's Hypothesis, 302
    - (c) The Theory of the Mechanism of Pricing, 305
    - (d) Codification of Value and Price Theory in the *Wealth of Nations*, 307
- 4. The Quantity Theory, 311
    - (a) Bodin's Explanation of the Price Revolution, 312
    - (b) Implications of the Quantity Theorem, 312
- 5. Credit and Banking, 317
    - (a) Credit and the Concept of Velocity: Cantillon, 318
    - (b) John Law: Ancestor of the Idea of a Managed Currency, 321
- 6. Capital, Saving, Investment, 322
- 7. Interest, 327
    - (a) Influence of the Scholastic Doctors, 328
    - (b) Barbon: 'Interest is the Rent of Stock,' 329
    - (c) Shift of Analytic Task from Interest to Profit, 330
    - (d) Turgot's Great Performance, 332

CHAPTER 7 THE 'MERCANTILIST' LITERATURE 335
- 1. Interpretation of the 'Mercantilist' Literature, 335
- 2. Export Monopolism, 338
- 3. Exchange Control, 340
- 4. The Balance of Trade, 345
    - (a) The Practical Argument: Power Politics, 346
    - (b) The Analytic Contribution, 347
    - (c) The Balance-of-Trade Concept as an Analytic Tool, 352
    - (d) Serra, Malynes, Misselden, Mun, 353
    - (e) Three Erroneous Propositions, 359
- 5. Analytic Progress from the Last Quarter of the Seventeenth Century: Josiah Child to Adam Smith, 362
    - (a) Concept of the Automatic Mechanism, 365
    - (b) Foundations of a General Theory of International Trade, 367
    - (c) General Tendency toward Freer Trade, 370
    - (d) Benefits from Territorial Division of Labor, 373

PART III

FROM 1790 TO 1870

CHAPTER 1 INTRODUCTION AND PLAN 379
- 1. Coverage, 379
- 2 Paraphernalia, 380
- 3. Plan of the Part, 383
- 4. Concerning the Marxist System, 383

CHAPTER 2 SOCIO-POLITICAL BACKGROUNDS 393
1. Economic Development, 396
2. Free Trade and Foreign Relations, 397
3. Domestic Policy and Sozialpolitik, 399
4. Gladstonian Finance, 402
5. Gold, 405

CHAPTER 3 THE INTELLECTUAL SCENERY 407
1. The Zeitgeist of the Period and Its Philosophy, 407
    (a) Utilitarianism, 407
    (b) German Philosophy, 411
    (c) Comtist Positivism, 415
2. Romanticism and Historiography, 418
    (a) Romanticism, 418
    (b) Historiography, 424
3. Sociology and Political Science: Environmentalism, 428
    (a) The Natural-Law Sociology of Government and Politics, 428
    (b) The Historians' Sociology of Government and Politics, 431
    (c) Environmentalism, 434
4. Evolutionism, 435
    (a) Philosophers' Evolutionism, 436
    (b) Marxist Evolutionism, 438
    (c) Historians' Evolutionism, 442
    (d) The Intellectualist Evolutionism of Condorcet and Comte, 442
    (e) Darwinian Evolutionism, 444
5. Psychology and Logic, 446
    (a) Associationist and Evolutionist Psychology, 446
    (b) Logic, Epistemology, and Cognate Fields, 448
    (c) J. S. Mill's *Logic*, 449
6. Pre-Marxian Socialism, 452
    (a) Associationist Socialism, 454
    (b) Anarchism, 457
    (c) Saint-Simonist Socialism, 460

CHAPTER 4 REVIEW OF THE TROOPS 463
1. The Men Who Wrote above Their Time, 463
2. The Ricardians, 469
3. Malthus, Senior, and Some of Those Who Also Ran, 480
    (a) Malthus, 480
    (b) Archbishop Whately and Professor Senior, 483
    (c) Some of Those Who Also Ran, 486
4. France, 490
5. Germany, 501
6. Italy, 510
7. United States, 514
8. Factual Work, 519
    (a) Tooke's *History of Prices*, 520
    (b) Collection and Interpretation of Statistical Materials, 521
    (c) Development of Statistical Methods, 524

CHAPTER 5 GENERAL ECONOMICS: A CROSS SECTION 527
1. J. S. Mill and his *Principles*. Fawcett and Cairnes, 527
2. Scope and Method: What Economists Thought They Were Doing, 534
    (a) Definitions of the Science, 534
    (b) Methodology, 536
    (c) The Science and the Art, 540
3. What Mill's Readers Actually Got, 541
4. The Institutional Frame of the Economic Process, 544
    (a) The Institutions of Capitalist Society, 544
    (b) The State in 'Classic' Economics, 548
    (c) The Nation and the Classes, 550
5. The 'Classic' Schema of the Economic Process, 554
    (a) The Actors, 554
    (b) The Agents, 557
    (c) The Model, 561
6. The 'Classic' Conception of Economic Development, 570

CHAPTER 6 GENERAL ECONOMICS: PURE THEORY 575
1. Axiomatics. Senior's Four Postulates, 575
    (a) The First Postulate, 576
    (b) The Second Postulate: the Principle of Population, 578
    (c) The Fourth Postulate: Diminishing Returns, 584
2. Value, 588
    (a) Ricardo and Marx, 590
    (b) The Opponents of the Labor Quantity Theory of Value, 598
    (c) J. S. Mill's Half-Way House, 603
3. The Theory of International Values, 605
4. Say's Law of Markets, 615
5. Capital, 625
    (a) Terminological Squabbles about Wealth and Income, 625
    (b) The Structure of Physical Capital, 631
    (c) Senior's Contributions, 637
    (d) J. S. Mill's Fundamental Propositions Respecting Capital, 640
6. The Distributive Shares, 645
    (a) Profits, 645
    (b) Marx's Exploitation Theory of Interest, 647
    (c) Marx, West, and Ricardo on the Falling Rate of Profit, 651
    (d) The Productivity Theories of Interest, 655
    (e) The Abstinence Theory of Interest, 659
    (f) The Wage-Fund Doctrine, Precursor of Modern Aggregative Analysis, 662
    (g) Rent, 671
    (h) Distributive Shares and Technological Advance, 679

CHAPTER 7 MONEY, CREDIT, AND CYCLES 688
1. England's Problems, 688
    (a) War Inflation, 1793-1815, 690

    - (b) The Question of the Standard, 692
    - (c) Bank Reform, 694
- 2. Fundamentals, 698
- 3. Gleanings from the Discussions on Inflation and Resumption, 706
- 4. The Theory of Credit, 717
    - (a) Credit, Prices, Interest, and Forced Savings, 718
    - (b) Gains from the Controversy about Peel's Act of 1844, 725
- 5. Foreign Exchange and International Gold Movements, 731
- 6. 'The' Business Cycle, 738

Part IV

FROM 1870 TO 1914 (AND LATER)

CHAPTER 1 Introduction and Plan 753

- 1. Coverage, 753
- 2. Paraphernalia, 754
- 3. Plan of the Part, 757

CHAPTER 2 Background and Patterns 759

- 1. Economic Development, 759
- 2. The Defeat of Liberalism, 761
- 3. Policies, 766
    - (a) Free Trade and Foreign Policy, 766
    - (b) Domestic Policy and Sozialpolitik, 767
    - (c) Fiscal Policy, 769
    - (d) Money, 770
- 4. Art and Thought, 771
    - (a) Bourgeois Civilization and Its Recalcitrant Offspring, 771
    - (b) Bourgeois Civilization and Its Philosophy, 772

CHAPTER 3 Some Developments in Neighboring Fields 781

- 1. History, 781
- 2. Sociology, 783
    - (a) Historical Sociology, 785
    - (b) Prehistorical-Ethnological Sociology, 786
    - (c) Biological Schools, 788
    - (d) Autonomous Sociology, 792
- 3. Psychology, 796
    - (a) Experimental Psychology, 796
    - (b) Behaviorism, 797
    - (c) Gestalt Psychology, 798
    - (d) Freudian Psychology, 798
    - (e) Social Psychology, 799

CHAPTER 4 Sozialpolitik and the Historical Method 800

- 1. Sozialpolitik, 800
    - (a) Influence upon Analytic Work, 801
    - (b) Verein für Sozialpolitik, 803
    - (c) The Problem of 'Value Judgments,' 804

2. Historism, 807
    (a) The 'Older' Historical School, 808
    (b) The 'Younger' Historical School, 809
    (c) The Methodenstreit, 814
    (d) The 'Youngest' Historical School: Spiethoff, Sombart, and M. Weber, 815
    (e) Economic History and Historical Economics in England, 821

CHAPTER 5 THE GENERAL ECONOMICS OF THE PERIOD: MEN AND GROUPS 825
1. Jevons, Menger, Walras, 825
2. England: The Marshallian Age, 829
    (a) Edgeworth, Wicksteed, Bowley, Cannan, and Hobson, 830
    (b) Marshall and His School, 833
3. France, 840
4. Germany and Austria, 843
    (a) The Austrian or Viennese School, 844
    (b) The Elder Statesmen, 850
    (c) The Representatives, 850
5. Italy, 855
    (a) The Elder Statesmen, 856
    (b) Pantaleoni, 857
    (c) Pareto, 858
6. The Netherlands and the Scandinavian Countries, 861
7. The United States, 863
    (a) The Men Who Prepared the Ground, 865
    (b) Clark, Fisher, and Taussig, 867
    (c) A Few More Leading Figures, 873
8. The Marxists, 877
    (a) Marxism in Germany, 879
    (b) Revisionism and the Marxist Revival, 882

CHAPTER 6 GENERAL ECONOMICS: ITS CHARACTER AND CONTENTS 886
1. Outposts, 886
    (a) The Sociological Framework of General Economics, 886
    (b) Population, 889
2. The Vision, Enterprise, and Capital, 891
    (a) The Vision, 892
    (b) Enterprise, 893
    (c) Capital, 898
3. The Revolution in the Theory of Value and Distribution, 909
    (a) The Theory of Exchange Value, 911
    (b) Cost, Production, Distribution, 912
    (c) Interdependence and Equilibrium, 918
4. Marshall's Attitude and Real Cost, 920
5. Interest, Rent, Wages, 924
    (a) Interest, 924
    (b) Rent, 932
    (c) Wages, 939

6. The Contribution of the Applied Fields, 944
    (a) International Trade [Heading only; section not written.], 945
    (b) Public Finance [Not finished.], 945
    (c) Labor Economics, 946
    (d) Agriculture [Heading only; section not written.], 948
    (e) Railroads, Public Utilities, 'Trusts,' and Cartels, 948

CHAPTER 7 EQUILIBRIUM ANALYSIS 951

1. Fundamental Unity of the Period's Economic Theory, 952
2. Cournot and the 'Mathematical School': Econometrics, 954
    (a) The Service Mathematics Rendered to Economic Theory, 955
    (b) The Contribution of Cournot, 958
3. The Concept of Equilibrium, 963
    (a) Statics, Dynamics; the Stationary State, Evolution, 963
    (b) Determinateness, Equilibrium, and Stability, 967
4. The Competitive Hypothesis and the Theory of Monopoly, 972
    (a) The Competitive Hypothesis, 973
    (b) The Theory of Monopoly, 975
    (c) Oligopoly and Bilateral Monopoly, 979
5. The Theory of Planning and of the Socialist Economy, 985
6. Partial Analysis, 990
    (a) The Marshallian Demand Curve, 991
    (b) Elasticity Concepts, 992
    (c) Concepts Useful for General Analysis, 994
7. The Walrasian Theory of General Equilibrium, 998
    (a) Walras' Conceptualization, 999
    (b) The Theory of Exchange, 1003
    (c) Determinateness and Stability of Simple Exchange, 1004
    (d) Walras' Theory of Production, 1009
    (e) The Introduction of Capital Formation and of Money, 1016
8. The Production Function, 1026
    (a) The Meaning of the Concept, 1027
    (b) The Evolution of the Concept, 1032
    (c) The Hypothesis of First-Order Homogeneity, 1039
    (d) Increasing Returns and Equilibrium, 1045
    (e) Tendency toward Zero Profits, 1048

APPENDIX TO CHAPTER 7

NOTE ON THE THEORY OF UTILITY, 1053

1. The Earlier Developments, 1054
2. Beginnings of the Modern Development, 1055
3. The Connection with Utilitarianism, 1056
4. Psychology and the Utility Theory, 1057
5. Cardinal Utility, 1060
6. Ordinal Utility, 1062

7. The Consistency Postulate, 1066
8. Welfare Economics, 1069

CHAPTER 8 MONEY, CREDIT, AND CYCLES 1074

1. Practical Problems, 1074
   (a) The Gold Standard, 1075
   (b) Bimetallism, 1076
   (c) International Monetary Co-operation, 1076
   (d) Stabilization and Monetary Management, 1077
2. Analytic Work, 1080
   (a) Walras, 1082
   (b) Marshall, 1083
   (c) Wicksell, 1085
   (d) The Austrians, 1085
3. Fundamentals, 1086
   (a) Nature and Functions of Money, 1086
   (b) Knapp's *State Theory of Money*, 1090
4. The Value of Money: Index Number Approach, 1091
   (a) Early Work, 1092
   (b) The Role of the Economic Theorists, 1092
   (c) Haberler, Divisia, and Keynes, 1094
5. The Value of Money: the Equation of Exchange and the 'Quantity Approach,' 1095
   (a) The Definition of the Concepts, 1096
   (b) Distinction between the Equation of Exchange and the Quantity Theory, 1099
   (c) Purchasing Power Parity and the Mechanism of International Payments, 1106
6. The Value of Money: the Cash Balance and Income Approaches, 1108
   (a) The Cash Balance Approach, 1108
   (b) The Income Approach, 1109
7. Bank Credit and the 'Creation' of Deposits, 1110
8. Crises and Cycles: the Monetary Theories, 1117
9. Non-Monetary Cycle Analysis, 1122
   (a) Juglar's Performance, 1123
   (b) Common Ground and Warring 'Theories,' 1125
   (c) Other Approaches, 1132

PART V

CONCLUSION

A SKETCH OF MODERN DEVELOPMENTS

CHAPTER 1 INTRODUCTION AND PLAN 1139

1. Plan of the Part, 1139
2. The Progress of Theoretical Economics during the Last Twenty-five Years, 1140
   (a) Introductory Lecture on the Scope of the Course, 1140
   (b) The Marshall-Wicksell System and Its Development, 1142

(c) Economic Dynamics, 1142
(d) Income Analysis, 1143
(e) Summary of the Course, 1144
3. Background and Patterns, 1145

CHAPTER 2 DEVELOPMENTS STEMMING FROM THE MARSHALL-WICKSELL APPARATUS 1148
1. The Modern Theory of Consumers' Behavior and the 'New' Theory of Production, 1148
2. Theory of the Individual Firm and Monopolistic Competition, 1150

CHAPTER 3 ECONOMICS IN THE 'TOTALITARIAN' COUNTRIES 1153
1. Germany, 1154
2. Italy, 1156
3. Russia, 1157

CHAPTER 4 DYNAMICS AND BUSINESS CYCLE RESEARCH 1160
1. Dynamizing Aggregative Theory: Macrodynamics, 1161
2. The Statistical Complement: Econometrics, 1162
3. The Interaction of Macrodynamics and Business Cycle Research, 1163

CHAPTER 5 KEYNES AND MODERN MACROECONOMICS 1170
1. Comments on the Wider Aspects of Keynes's Work, 1171
2. The Analytic Apparatus of the *General Theory*, 1174
3. The Impact of the Keynesian Message, 1180

PART I

INTRODUCTION

SCOPE AND METHOD

CHAPTER 1

[Introduction and Plan]

1. PLAN OF THE BOOK 3
2. WHY DO WE STUDY THE HISTORY OF ECONOMICS? 4
3. BUT IS ECONOMICS A SCIENCE? 6

1. PLAN OF THE BOOK

BY HISTORY of Economic Analysis I mean the history of the intellectual efforts that men have made in order to *understand* economic phenomena or, which comes to the same thing, the history of the analytic or scientific aspects of economic thought. Part II of this book will describe the history of those efforts from the earliest discernible beginnings up to and including the last two or three decades of the eighteenth century. Part III will go on through the period that may be described, though only very roughly, as the period of the English 'classics'—to about the early 1870's. Part IV will present an account of the fortunes of analytic or scientific economics from (speaking again very roughly) the end of the 'classic' period to the First World War, though the history of some topics will, for the sake of convenience, be carried to the present time. These three Parts constitute the bulk of the book and embody the bulk of the research that went into it. Part V is merely a sketch of modern developments, relieved of some of its cargo by the anticipations in Part IV that have been just mentioned, and aims at nothing more ambitious than helping the reader to understand how modern work links up with the work of the past.

In facing the huge task that has been attempted rather than performed in this book we become aware immediately of an ominous fact. Whatever the problems that, to snare the unwary, lurk below the surface of the history of any science, its historian is in other cases at least sure enough of his subject to be able to start right away. This is not so in our case. Here, the very ideas of economic analysis, of intellectual effort, of science, are 'quenched in smoke,' and the very rules or principles that are to guide the historian's pen are open to doubt and, what is worse, to misunderstanding. Therefore, Parts II to V will be prefaced by a Part I that is to explain as fully as space permits my views on the nature of my subject and some of the conceptual arrangements I propose to use. It has further seemed to me that a number of topics should be included that pertain to the Sociology of Science—to the theory of science considered as a social phenomenon. But observe: these things stand here in order to convey some information about the principles I am going to adopt or about the atmosphere of this book. Though reasons will be given for my adopting them, they cannot be fully established here. They are merely to facilitate the understanding of what I have tried to do and to enable the reader to lay the book aside if this atmosphere be not to his taste.

2. Why Do We Study the History of Economics?

Well, why do we study the history of *any* science? Current work, so one would think, will preserve whatever is still useful of the work of preceding generations. Concepts, methods, and results that are not so preserved are presumably not worth bothering about. Why then should we go back to old authors and rehearse outmoded views? Cannot the old stuff be safely left to the care of a few specialists who love it for its own sake?

There is much to be said for this attitude. It is certainly better to scrap outworn modes of thought than to stick to them indefinitely. Nevertheless, we stand to profit from visits to the lumber room provided we do not stay there too long. The gains with which we may hope to emerge from it can be displayed under three heads: pedagogical advantages, new ideas, and insights into the ways of the human mind. We shall take these up in turn, at first without special reference to economics and then add, under a fourth head, some reasons for believing that in economics the case for a study of the history of analytic work is still stronger than it is for other fields.

First, then, teachers or students who attempt to act upon the theory that the most recent treatise is all they need will soon discover that they are making things unnecessarily difficult for themselves. Unless that recent treatise itself presents a minimum of historical aspects, no amount of correctness, originality, rigor, or elegance will prevent a sense of *lacking direction and meaning* from spreading among the students or at least the majority of students. This is because, whatever the field, the problems and methods that are in use at any given time embody the achievements and carry the scars of work that has been done in the past under entirely different conditions. The significance and validity of both problems and methods cannot be fully grasped without a knowledge of the previous problems and methods to which they are the (tentative) response. Scientific analysis is not simply a logically consistent process that starts with some primitive notions and then adds to the stock in a straight-line fashion. It is not simply progressive discovery of an objective reality—as is, for example, discovery in the basin of the Congo. Rather it is an incessant struggle with creations of our own and our predecessors' minds and it 'progresses,' if at all, in a criss-cross fashion, not as logic, but as the impact of new ideas or observations or needs, and also as the bents and temperaments of new men, dictate. Therefore, any treatise that attempts to render 'the present state of science' really renders methods, problems, and results that are historically conditioned and are meaningful only with reference to the historical background from which they spring. To put the same thing somewhat differently: the state of any science at any given time implies its past history and cannot be satisfactorily conveyed without making this implicit history explicit. Let me add at once that this pedagogical aspect will be kept in mind throughout the book and that it will guide the choice of material for discussion, sometimes at the expense of other important criteria.

Second, our minds are apt to derive new inspiration from the study of the history of science. Some do so more than others, but there are probably few that do not derive from it any benefit at all. A man's mind must be indeed sluggish if, standing back from the work of his time and beholding the wide mountain ranges of past thought, he does not experience a widening of his own horizon. The productivity of this experience may be illustrated by the fact that the fundamental ideas that eventually developed into the theory of (special) relativity occurred first in a book on the history of mechanics.[1] But, besides inspiration every one of us may glean lessons from the history of his science that are useful, even though sometimes discouraging. We learn about both the futility and the fertility of controversies; about detours, wasted efforts, and blind alleys; about spells of arrested growth, about our dependence on chance, about how not to do things, about leeways to make up for. We learn to understand why we are as far as we actually are and also why we are not further. And we learn *what succeeds and how and why*—a question to which attention will be paid throughout this book.

Third, the highest claim that can be made for the history of any science or of science in general is that it teaches us much about the ways of the human mind. To be sure, the material it presents bears only upon a particular kind of intellectual activity. But within this field its evidence is almost ideally complete. It displays logic in the concrete, logic in action, logic wedded to vision and to purpose. Any field of human action displays the human mind at work but in no other field do we get so near the actual methods of working because in no other field do people take so much trouble to report on their mental processes. Different men have behaved differently in this respect. Some, like Huyghens, were frank; others, like Newton, were reticent. But even the most reticent of scientists are bound to reveal their mental processes because scientific—unlike political—performance is self-revelatory by nature. It is for this reason mainly that it has been recognized many times—from Whewell and J. S. Mill to Wundt and Dewey—that the general science of science (the German *Wissenschaftslehre*) is not only applied logic but also a laboratory for pure logic itself. That is to say, scientific habits or rules of procedure are not merely to be judged by logical standards that exist independently of them; they contribute something to, and react back upon, these logical standards themselves. To convey the point by the useful device of exaggeration: a sort of pragmatic or descriptive logic may be abstracted from observation and formulation of scientific procedures—which of course *involve*, or merge into, the study of the history of sciences.

Fourth, it stands to reason that the preceding arguments, at least the ones that have been presented under the first two headings, apply with added force to the special case of economics. We shall attend presently to the implications of the obvious fact that the subject matter of economics is itself a unique historical process (see sec. 3 below) so that, to a large extent, the economics of different epochs deal with different sets of facts and problems.

---

[1] Ernst Mach, *Die Mechanik in ihrer Entwicklung: historisch-kritisch dargestellt* (1st ed., 1883; see Appendix, by J. Petzoldt, to the 8th ed.); English trans. by T. J. McCormack, containing additions and alterations up to the 9th (the final) ed., 1942.

This fact alone would suffice to lend increased interest to doctrinal history. But let us discard it for the moment in order to avoid repetition and to emphasize another fact. As we shall see, scientific economics does not lack historical continuity. It is in fact our main purpose to describe what may be called the process of the Filiation of Scientific Ideas—the process by which men's efforts to understand economic phenomena produce, improve, and pull down analytic structures in an unending sequence. And it is one of the main theses to be established in this book that *fundamentally* this process does not differ from the analogous processes in other fields of knowledge. But, for reasons that it is also one of our purposes to make clear, this filiation of ideas has met with more inhibitions in our field than it has in almost all others. Few people, and least of all we economists ourselves, are prone to offer us congratulations on our intellectual achievements. Moreover our performance is, and always was, not only modest but also disorganized. Methods of fact-finding and analysis that are and were considered substandard or wrong on principle by some of us do prevail and have prevailed widely with others. Although it is possible nevertheless—as I shall try to show—to speak for every epoch of established professional opinion *on scientific topics* and although this opinion has often stood the test of being proof against strong differences in political views, we cannot speak with as much confidence about it as can physicists or mathematicians. In consequence we cannot, or at least we do not, trust one another to sum up 'the state of the science' in an equally satisfactory manner. And the obvious remedy for the shortcomings of summarizing works is the study of doctrinal history: much more than in, say, physics is it true in economics that modern problems, methods, and results cannot be fully understood without some knowledge of how economists have come to reason as they do. In addition, much more than in physics have results been lost on the way or remained in abeyance for centuries. We shall meet with instances that are little short of appalling. Stimulating suggestions and useful if disconcerting lessons are much more likely to come to the economist who studies the history of his science than to the physicist who can, in general, rely on the fact that almost nothing worth while has been lost of the work of his predecessors. Why, then, not start in at once upon another story of intellectual conquest?

3. But Is Economics a Science?

The answer to the question that heads this section depends of course on what we mean by 'science.' Thus, in everyday parlance as well as in the lingo of academic life—particularly in French and English-speaking countries—the term is often used to denote mathematical physics. Evidently, this excludes all social sciences and also economics. Nor is economics as a whole a science if we make the use of methods similar to those of mathematical physics the defining characteristic (*definiens*) of science. In this case only a small part of economics is 'scientific.' Again, if we define science according to the slogan 'Science is Measurement,' then economics is scientific in some of its parts and not in others. There should be no susceptibilities concerning 'rank' or 'dignity' about this: to call a field a science should not spell either a compliment or the reverse.

For our purpose, a very wide definition suggests itself, to wit: a science is any kind of knowledge that has been the object of conscious efforts to improve it.[1] Such efforts produce habits of mind—methods or 'techniques'—and a command of facts unearthed by these techniques which are beyond the range of the mental habits and the factual knowledge of everyday life. Hence we may also adopt the practically equivalent definition: a science is any field of knowledge that has developed specialized techniques of fact-finding and of interpretation or inference (analysis). Finally, if we wish to emphasize sociological aspects, we may formulate still another definition, which is also practically equivalent to the other two: a science is any field of knowledge in which there are people, so called research workers or scientists or scholars, who engage in the task of improving upon the existing stock of facts and methods and who, in the process of doing so, acquire a command of both that differentiates them from the 'layman' and eventually also from the mere 'practitioner.' Many other definitions would be just as good. Here are two which I add without further explanations: (1) science is refined common sense; (2) science is tooled knowledge.

Since economics uses techniques that are not in use among the general public, and since there are economists to cultivate them, economics is obviously a science within our meaning of the term. It seems to follow that to write the history of those techniques is a perfectly straightforward task about which there should be no doubts or qualms. Unfortunately this is not so. We are not yet out of the wood; in fact, we are not yet in it. A number of obstacles will have to be removed before we can feel sure of our ground—the most serious one carrying the label Ideology. This will be done in the subsequent chapters of this Part. Just now, a few comments will be presented on our definition of science.

First of all we must meet what the reader presumably considers a fatal objection. Science being tooled knowledge, that is, being defined by the criterion of using special techniques, it seems as though we should have to include, for instance, the magic practiced in a primitive tribe if it uses techniques that are not generally accessible and are being developed and handed on within a circle of professional magicians. And *of course* we ought to include it on principle. This is so because magic, and practices that in the relevant aspect do not differ fundamentally from magic, sometimes shade off into what modern man recognizes as scientific procedure by imperceptible steps: astrology was astronomy's mate until the beginning of the seventeenth century.

---

[1] We shall reserve the term Exact Science for the second of the meanings of the word Science enumerated above, i.e. for sciences that use methods more or less similar in logical structure to those of mathematical physics. The term Pure Science will be used in contrast to Applied Science (the French used the same term, for instance, *mécanique* or *économie pure*, but also the term *mécanique* or *économie rationnelle*; the Italian equivalent is *meccanica* or *economia pura*, the German *reine Mechanik* or *Ökonomie*).

There is however another and still more compelling reason. The exclusion of any kind of tooled knowledge would amount to declaring our own standards to be absolutely valid for all times and places. But this we cannot do.[2] In practice we have indeed no choice but to interpret and to appraise every piece of tooled knowledge, past as well as present, in the light of our standards, since we have no others. They are the results of a development of more than six centuries,[3] during which the realm of scientifically admissible procedures or techniques has been more and more restricted in the sense that more and more procedures or techniques have been ruled out as inadmissible. We mean this critically restricted realm only when we speak of 'modern' or 'empirical' or 'positive' [4] science. Its rules of procedure differ in different departments of science and, as we have already seen above, are never beyond doubt. Broadly, however, they may be described by two salient characteristics: they reduce the facts we are invited to accept *on scientific grounds* to the narrower category of 'facts verifiable by observation or experiment'; and they reduce the range of admissible methods to 'logical inference from verifiable facts.' Henceforth we shall put ourselves on this standpoint of empirical science, at least so far as its principles are recognized in economics. But in doing so we must bear this in mind: although we are going to interpret doctrines from this standpoint we do not claim any 'absolute' validity for it; and although, reasoning from this standpoint, we may describe any given propositions or methods as invalid—always of course with reference to the historical conditions in which they were formulated—we do not therefore exclude them from the realm of scientific thought in our original (broadest) sense of the word or, to put it somewhat differently, deny to them scientific character[5]—which must be appraised, if at all, according to the 'professional' standards of every time and place.

---

[2] The best way of convincing ourselves of this is to observe that our rules of procedure are, and presumably always will be, subject to controversy and in a state of flux. Consider, e.g., the following case. Nobody has proved that every even number can be expressed as the sum of two prime numbers, although no even number that cannot has been discovered so far. Suppose now that this proposition someday leads to a contradiction with another proposition which we agree to accept. Would it follow from this that *there exists* an even number that is not the sum of two primes? 'Classic' mathematicians would answer Yes, 'intuitionist' mathematicians (such as Kronecker and Brouwer) would answer No; that is, the former admit and the latter refuse to admit the validity of what are called *indirect proofs of existence theorems*, which are widely used in many fields and also in pure economics. Evidently, the mere possibility of such a difference of opinion on what constitutes valid proof suffices to show, among other things, that our own rules cannot be accepted as the last word on scientific procedure.

[3] This estimate refers to Western Civilization alone and in addition takes account of Greek developments only so far as they entered scientific thought in western Europe from the thirteenth century on, as an inheritance, but not of those developments themselves. As a landmark, we choose the *Summa Theologica* of St. Thomas Aquinas, which excludes revelation from the *philosophicae disciplinae*, that is, from all sciences except supernatural theology (*sacra doctrina;* natural theology is one of the *philosophicae disciplinae*). This was the earliest and most important step in methodological criticism taken in Europe after the breakdown of the Graeco-Roman world. It will be shown below how exclusion of revelation from all sciences except the *sacra doctrina* was coupled by St. Thomas with the exclusion from them of appeal to authority as an admissible *scientific* method.

[4] The word 'positive' as used in this connection has nothing whatever to do with philosophical positivism. This is the first of many warnings that will have to be issued in this book against the dangers of confusion that arise from the use, for entirely different things, of the same word by writers who themselves sometimes confuse the things. The point is important and so I shall mention instances at once: rationalism, rationalization, relativism, liberalism, empiricism.

Second, our original definition ('tooled knowledge') indicates the reason why it is in general impossible to date—even by decades—the origins, let alone the 'foundation,' of a science as distinguished from the origins of a particular method or the foundation of a 'school.' Just as sciences grow by slow accretion when they have come into existence, so they emerge by slow accretion, gradually differentiating themselves, under the influence of favorable and inhibiting environmental and personal conditions, from their common-sense background and sometimes also from other sciences. Research into the past, clarifying those conditions, can and does reduce the time range within which it is in each case about equally justifiable to aver or to deny the existence of a body of scientific knowledge. But no amount of research can eliminate altogether a zone of doubt that has always been broadened by the historian's personal equation. As regards economics, bias or ignorance alone can explain such statements as that A. Smith or F. Quesnay or Sir William Petty or anyone else 'founded' that science, or that the historian should begin his report with one of them. But it must be admitted that economics constitutes a particularly difficult case, because common-sense knowledge goes in this field much farther relatively to such scientific knowledge as we have been able to achieve, than does common-sense knowledge in almost any other field. The layman's knowledge that rich harvests are associated with low prices of foodstuffs or that division of labor increases the efficiency of the productive process are obviously prescientific and it is absurd to point to such statements in old writings as if they embodied discoveries. The primitive apparatus of the theory of demand and supply is scientific. But the scientific achievement is so modest, and common sense and scientific knowledge are logically such close neighbors in this case, that any assertion about the precise point at which the one turned into the other must of necessity remain arbitrary. I use this opportunity to advert to a cognate problem.

To define science as tooled knowledge and to associate it with particular groups of men is almost the same thing as emphasizing the obvious importance of specialization of which the individual sciences are the (relatively late) result.[6] But this process of specialization has never gone on according to any rational plan—whether explicitly preconceived or only objectively present—so that science as a whole has never attained a logically consistent architecture; it is a tropical forest, not a building erected according to blueprint. Individuals and groups have followed leaders or exploited methods or have been lured on by their problems, as it were, cross country, as has been already explained in Section 2. One of the consequences of this is that the frontiers of the individual sciences or of most of them are incessantly shifting and that there is no point in trying to define them *either by subject or by method.* This applies particularly to economics, which is not a science in the sense in which acoustics is one, but is rather an agglomeration of ill-co-ordinated and overlapping fields of research in the same sense as is 'medicine.' Accordingly, we shall indeed discuss other people's definitions—primarily for the purpose of wondering at their inadequacies—but we shall not adopt one for ourselves. Our closest approach to doing so will consist in the enumeration presented below of the main 'fields' now recognized in teaching practice. But even this epideiktic definition [7] must be understood to carry no claim to completeness. In addition we must always leave open the possibility that, in the future, topics may be added to or dropped from any complete list that might be drawn up as of today.

---

[5] All this is very inadequate and of course completely fails to do justice to the deep problems that we have been touching superficially. Since, however, it is all that can be done in the available space, I wish to add only that the interpretation above will be seen to be as far as possible removed from (a) a claim to professorial omniscience; (b) a wish to 'grade' the cultural contents of the thought of the past according to present standards; and especially (c) to appraise anything but techniques of analysis. Some related points will become clearer as we go along.

Third, our definition implies nothing about the motives that impel men to exert themselves in order to improve upon the existing knowledge in any field. In another connection we shall presently return to this subject. For the moment we only note that the scientific character of a given piece of analysis is independent of the motive for the sake of which it is undertaken. For instance, bacteriological research is scientific research and it does not make any difference to its procedures whether the investigator embarks upon it in order to serve a medical purpose or any other. Similarly, if an economist investigates the practices of speculation by methods that meet the scientific standards of his time and environment, the results will form part of the scientific fund of economic knowledge, irrespective of whether he wishes to use them for recommending regulatory legislation or to defend speculation against such legislation or merely to satisfy his intellectual curiosity. Unless he allows his purpose to distort his facts or his reasoning, there is no point in our refusing to accept his results or to deny their scientific character on the ground that we disapprove of his purpose. This implies that any arguments of a scientific character produced by 'special pleaders'—whether they are paid or not for producing them—are for us just as good or bad as those of 'detached philosophers,' if the latter species does indeed exist. Remember: occasionally, it may be an interesting question to ask *why* a man says what he says; but whatever the answer, it does not tell us anything about whether what he says is true or false. We take no stock in the cheap device of political warfare—unfortunately too common also among economists—of arguing about a proposition by attacking or extolling the motives of the man who sponsors it or the interest for or against which the proposition seems to tell.

---

[6] Let me add at once that within such groups of fellow workers a specialized language is sure to develop that becomes increasingly un-understandable to the lay public. This effort saving device could even be used as a criterion by which to recognize the presence of a science if it were not the fact that very often it is adopted, only long after a science in our sense has grown to respectable size, under pressure of the intolerable inconvenience incident to using concepts of everyday life that serve but ill the purposes of analysis. Economists in particular, much to the detriment of their field, have attached unreasonable importance to being understood by the general public, and this public even now displays equally unreasonable resentment toward any attempt to adopt a more rational practice.

[7] An epideiktic definition is the definition of a concept, say the concept 'elephant,' by pointing to a specimen of the class denoted by the concept.

CHAPTER 2

Interlude I: [The Techniques of Economic Analysis]

[1. Economic History] 12
[2. Statistics] 13
[3. 'Theory'] 14
[4. Economic Sociology] 20
[5. Political Economy] 21
[6. Applied Fields] 22

THE LAST PARAGRAPH of the preceding chapter points toward momentous problems, which will, under the heading of Sociology of Science, be touched upon in Chapter 4. Now we break off our argument and turn aside in order to hunt two hares whose paths diverge sometimes in a disconcerting manner: on the one hand, it is necessary to define the relations of economics to some of the fields of tooled knowledge that have or have had influence upon it or have border zones in common with it [1] (ch. 3); on the other hand, it is convenient to use this opportunity to explain right now some of the concepts and principles that will govern our exposition of the history of economic analysis. This will be done in the current chapter.

Let us begin in a thoroughly common-sense manner. What distinguishes the 'scientific' economist from all the other people who think, talk, and write about economic topics is a command of techniques [2] that we class under three heads: history, statistics, and 'theory.' The three together make up what we shall call Economic Analysis. [Later in this chapter, J. A. S. added to these three a fourth fundamental field, Economic Sociology.]

[1. Economic History]

Of these fundamental fields, economic history—which issues into and includes present-day facts—is by far the most important. I wish to state right now that if, starting my work in economics afresh, I were told that I could study only one of the three but could have my choice, it would be economic history that I should choose. And this on three grounds. First, the subject matter of economics is essentially a unique process in historic time. Nobody can hope to understand the economic phenomena of any, including the present, epoch who has not an adequate command of historical *facts* and an adequate amount of historical *sense* or of what may be described as *historical experience.*[3] Second, the historical report cannot be purely economic but must inevitably reflect also 'institutional' facts that are not purely economic: therefore it affords the best method for understanding how economic and non-economic facts *are* related to one another and how the various social sciences *should* be related to one another.[4] Third, it is, I believe, the fact that most of the fundamental errors currently committed in economic analysis are due to lack of historical experience more often than to any other shortcoming of the economist's equipment. History must of course be understood to include fields that have acquired different names as a consequence of specialization, such as prehistoric reports and ethnology (anthropology).[5]

---

[1] This clumsy phrasing has been chosen in order to avoid the unrealistic suggestion of sharp and permanent border lines.

[2] The word 'technique' should be understood in a very wide sense: mere command of the facts of some field, systematically acquired and such as to be beyond the range of knowledge than can be gained by practicing in that field, is sufficient to constitute scientific level, even though cultivation of the field does not require any elaborate methods that the layman could not understand.

Two ominous consequences of the argument above should be noticed at once. First, since history is an important source—though not the only one—of the economist's material and since, moreover, the economist himself is a product of his own *and all preceding* time, economic analysis and its results are certainly affected by historical relativity[6] and the only question is how much. No worth while answer to this question can be got by philosophizing about it, but it will be one of our major concerns to work one out by detailed investigation. This is why sketches of 'the spirit of the times' and, in particular, of the politics of each period will preface our exposition of the economic analysis in the subsequent Parts. Second, we have to face the fact that, economic history being part of economics, the historian's techniques are passengers in the big bus that we call economic analysis. Derivative knowledge is always unsatisfactory. Hence, even economists who are not economic historians themselves and who merely read the historical reports written by others must understand how these reports came into being or else they will not be able to appraise the real meaning. We shall not be able to live up to the program that follows from this. In principle however let us remember: Latin palaeography, for instance, is one of the techniques of economic analysis.

[2. STATISTICS]

It stands to reason that for economics, statistics, that is, the statistical figure or series of figures must be of vital importance. In practice this has been recognized *at least* since the sixteenth and seventeenth centuries when a large part of the work of the Spanish *políticos*, for example, consisted in the collection and interpretation of statistical figures—not to mention the English econometricians, who were called political arithmeticians, and their fellow workers in France, Germany, and Italy.[1] We need statistics not only for explaining things but also in order to know precisely what there is to explain. But a comment has to be added that is analogous to the comment made in the preceding paragraph on the subject of history. It is impossible to understand statistical figures without understanding how they have been compiled. It is equally impossible to extract information from them or to understand the information that specialists extract for the rest of us without understanding the methods by which this is done—and the epistemological backgrounds of these methods. Thus, an adequate command of modern statistical methods is a necessary (but not a sufficient) condition for preventing the modern economist from producing nonsense, though very much more so in some fields than in others: our stake in these methods is too great for us to leave judgment on the virtues or shortcomings, say, of the variate-difference method to specialists, even if they were unanimous about it. Again, we shall not be able to live up to the program that follows from this. But again, we shall recognize, in principle at least: statistical methods are part of the tools of economic analysis even when not specially devised to meet its particular needs; and Jacques Bernoulli's *Ars conjectandi* or Laplace's *Théorie analytique* stand in the history of many sciences but they have their places also in the history of our own.[2]

---

[3] This does not render 'theory,' in the sense to be explained below, either impossible or useless—economic history itself needs its help.

[4] Owing to the unreliability of 'theories' on this subject, I personally believe the study of history to be not only the best but the only method for this purpose.

[5] In this book, unless warning to the contrary is given, anthropology means physical anthropology only. Above it has the usual meaning which makes it synonymous with the study of primitive tribes, their behavior patterns, language, and social institutions. We call this ethnology.

[6] This is one of several meanings of that much misused word, relativity. Here we mean by it no more than (a) that we cannot use more material than we have and that in consequence some or all of our results may not stand up in the light of further experience (a fact that must of course be duly allowed for in the interpretation of the economists of the past); and (b) that economists' interests in the problems of their epoch and also their attitudes to these problems condition their *general* views on economic phenomena. See ch. 4. This has nothing to do with philosophic relativism.

[3. 'THEORY']

The third fundamental field is 'theory.' This term carries many meanings but only two of them are relevant so far as our own usage in this book is concerned. The first and less important one makes theories synonymous with Explanatory Hypotheses. Such hypotheses are of course essential ingredients of historiography and statistics also. For instance, even the most fiercely factual historian, economic or other, can hardly avoid forming an explanatory hypothesis or theory, or several explanatory hypotheses or theories, on the origins of towns. The statistician must form a hypothesis or theory, say, on the joint distribution of the stochastic variables that enter into his problem. All that needs to be said about this is that it is an error—though a widespread one—to believe that the sole or main business of the economic theorist consists in formulating such hypotheses (some may wish to add: out of the blue sky).

---

[1] It is therefore only as a *curiosum* that we notice the fact that the simple and apparently unchallengeable statement in the first sentence of the paragraph above has been staunchly denied by some economists to this day.

[2] Lest the reader should throw up his hands in despair at the range of competence which the historical and statistical requirements seem to indicate, let me point out that these requirements can be easily fulfilled by every graduate student who has had a tolerably good undergraduate training in history or mathematics. Only the student without any training in either will have to realize that, as an all-round economist, he is suffering from a handicap and that he can move with assurance only within narrow portions of the science unless he is prepared to make up for his deficiencies by a heroic effort for which one or two years of graduate study are altogether inadequate. But it also takes more than that to become a scientifically competent lawyer or engineer or doctor.

Economic theory does something entirely different. It cannot indeed, any more than can theoretical physics, do without simplifying schemata or models that are intended to portray certain aspects of reality and take some things for granted in order to establish others according to certain rules of procedure. So far as our present argument is concerned, the things (propositions) that we take for granted may be called indiscriminately either hypotheses or axioms or postulates or assumptions or even principles,[1] and the things (propositions) that we think we have established by admissible procedure are called theorems. Of course a proposition may figure in one argument as a postulate and in another as a theorem. Now, hypotheses of this kind are also *suggested* by facts—they are framed with an eye to observations made—but in strict logic they are arbitrary creations of the analyst.[2] They differ from the hypotheses of the first kind in that they do not *embody* final results of research that are supposed to be interesting for their own sake, but are mere instruments or tools framed for the purpose of *establishing* interesting results. Moreover, framing them is no more all the economic theorist does than framing statistical hypotheses is all that the statistical theorist or in fact any theorist does. Just as important is the devising of the other gadgets by which results may be extracted from the hypotheses—all the concepts (such as 'marginal rate of substitution,' 'marginal productivity,' 'multiplier,' 'accelerator'), relations between concepts, and methods of handling these relations, all of which have nothing hypothetical about them.[3] And it is the sum total of such gadgets—inclusive of strategically useful assumptions—which constitutes economic theory. In Mrs. Robinson's unsurpassably felicitous phrase, economic theory is a box of tools.

The rationale of this conception of economic theory is very simple and the same as in all other departments of science. Experience teaches us that the phenomena of a given class—economic, biological, mechanical, electrical, and what not—are indeed individual occurrences each of which, as it occurs, reveals peculiarities of its own. But experience also teaches us that these individual occurrences have certain properties or aspects in common and that *a tremendous economy of mental effort may be realized if we deal with these properties or aspects, and with the problems they raise, once and for all.* For some purposes it is indeed necessary to analyze every individual case of pricing in an individual market, every case of income formation, every individual business cycle, every international transaction, and so on. But even where this is necessary we discover that we are using, in each case, concepts that occur in the analysis of all. Next we discover that all cases, or at least large sets of individual cases, display similar features which, and the implications of which, may be treated for all of them together by means of general schemata of pricing, income formation, cycles, international transactions, and so on. And finally we discover that these schemata are not independent of one another but related, so that there is advantage in ascending to a still higher level of 'generalizing abstraction' on which we construct a composite instrument or engine or organon of economic analysis—though not the only one, as we have seen—which functions *formally* in the same way, whatever the economic problem to which we may turn [4] it. Richard Cantillon's [5] work is the first in which awareness of this last truth is clearly discernible, though economists took over a century to realize all its possibilities—Léon Walras was in fact the first to do so (see below Part IV, ch. 6, sec. 5b).

---

[1] By 'principle' we shall mean in this book any statement that we (or the authors under discussion) do not propose to challenge. But it may be a proposition that we (they) have established as well as a proposition that we (they) have postulated or assumed. The same holds for the objectionable term 'law,' the emergence and use or misuse of which will have to be carefully considered: we speak of the 'law' of decreasing returns or of Keynes's 'law' of the propensity to consume, which are assumptions, but also of the Marxist 'law' of the falling rate of profit, which is a proposition that Marx thought he had established.

[2] To use J. H. Poincaré's simile: tailors can cut suits as they please; but of course they try to cut them to fit their customers.

[3] Example: theoretical mechanics proceeds upon a number of assumptions (or hypotheses in this sense); but evidently the list of these assumptions is not the whole of theoretical mechanics but only constitutes, where explicitly assembled, its first chapter.

Although it is neither possible nor desirable for us to embark upon an epistemology of economics and although some of the topics pertaining to that field will receive attention both in the subsequent chapters of this Part and in all the subsequent Parts, it will be helpful to insert here a few additional remarks in the hope that they will do something to scale down possible barriers between myself and my readers.

First, then, a qualification should be added to the preceding argument about the nature and functions of economic theory. This argument ran in terms which are applicable, substantially at least, to all sciences that have any all-purpose apparatus of analysis. But there are limits to this parallelism and the most important of them are represented by the two following facts. Economics lacks the benefits that physics derives from laboratory experiments—when economists talk about experimenting they mean something quite different from experimenting under laboratory conditions—but enjoys instead a source of information that is denied to physics, namely, man's extensive knowledge of the *meanings* of economic actions. This source of information is also a source of controversies that will bother us repeatedly on our journey. But its existence can hardly be denied. Now, when we speak, for example, of motives that are supposed to actuate individuals or groups, our source of information may be roughly identified with knowledge of psychic processes, conscious or subconscious, which it would be absurd not to use, although, as I shall never cease to emphasize, this is not the same thing as trespassing upon the field of professional psychology—any more than stating the 'law' of decreasing returns from land implies trespassing upon the realm of physics. There is, however, also another way of interpreting our knowledge of meanings which is more akin to logic. If I state, for example, that—under a number of conditions—instantaneous gains of a firm will be maximized at the output at which marginal cost equals marginal revenue (the latter equaling price in the case of pure competition), I may be said to be formulating the logic of the situation and a result that is true, just as is a rule of general logic, independently of whether or not anyone ever acts in conformity to it. This means that there is a class of economic theorems that are logical (not, of course, ethical or political) *ideals* or *norms*. And they evidently differ from another class of economic theorems that are directly based upon observations, for example, on observations as to how far expectations of employment opportunity affect workmen's expenditure on consumers' goods or how variations in wages affect the marriage rate. It would no doubt be possible to assimilate both types of theory by interpreting the logical norms also as 'purifying' generalizations from observational data, if need be, from observations that are subconsciously stored up by common experience. On the whole, however, it seems better not to do so but to recognize frankly that we have, or think we have, the ability to understand meanings and to represent the implications of these meanings by appropriately constructed schemata.

---

[4] The statement above is a brief rendering of E. Mach's doctrine that every (theoretical) science is a device for effecting economy of effort (*Denkökonomie*).

[5] See below Part II, ch. 4, sec. 2.

Second, the foregoing explanation may have done something toward exonerating me from the suspicion that I am tainted with Scientism. This term has been introduced by Professor von Hayek[6] to denote the uncritical copying of the methods of mathematical physics in the equally uncritical belief that these methods are of universal application and the peerless example for all scientific activity to follow. This history as a whole will answer the question whether there actually has been such uncritical copying of methods that have meaning only within the particular patterns of the sciences that developed them—*apart of course from programmatic utterances that have been numerous enough ever since the awe-inspiring successes of the physical sciences in the seventeenth century but mean next to nothing.* As regards the question of principle, there cannot be the slightest doubt that Hayek is right—and so were all who in the nineteenth century preceded him in uttering protests similar to his—in holding that the borrowing by economists of any method on the sole ground that it has been successful somewhere else is inadmissible, and that the rare and unimportant cases in which this has actually been done deserve what they get at his hands. Unfortunately this is not the real question. We have to ask what constitutes 'borrowing' before we can proceed to ask what constitutes illegitimate borrowing. And here we must beware of an optical illusion similar to the one that makes Marxists so reluctant to use such terms as price or cost or money or value of the services of land or even interest when speaking of a future socialist order: these terms denote concepts of general economic logic and seem to Marxists to be tainted with a capitalist meaning only because they are used also in capitalist society. Similarly, the concepts and procedures of 'higher' mathematics have indeed been first developed in connection with the physicist's problems, but this does not mean that there is anything specifically 'physicalist' about this particular kind of language.[7] But this also holds for some of the general concepts of physics, such as equilibrium potential or oscillator, or statics and dynamics, which turn up of themselves in economic analysis just as do systems of equations: what we borrow when we use, for example, the concept of an 'oscillator' is a word and nothing else. Two circumstances combine, however, to reinforce that optical illusion. On the one hand, physicists and mathematicians, when they hit upon those general concepts that occurred to us only later, not only baptized them but also worked out their logic. So long as this logic does not introduce anything 'physicalist' it would be waste of effort not to make use of it. On the other hand, students sometimes understand a physical analogy more readily than they do the economics of the case to be presented. Hence such analogies are often used in teaching. It therefore seems as though the things we are accused of borrowing are merely the reflexes of the fact that all of us, physicists or economists, have only one type of brain to work with and that this brain acts in ways that are to some extent similar whatever the task it tackles—the fact to which the Unity-of-Science movement owes its existence. This does not involve any mechanistic, deterministic or other '-istic' errors, or any neglect of the truth that 'to explain' means something different in the natural and in the social sciences, or finally any denial of the implications of the historical character of our subject matter.

---

[6] F. A. von Hayek, 'Scientism and the Study of Society,' *Economica*, August 1942, February 1943, and February 1944. This treatise—these articles are nothing less than a treatise—is strongly recommended both because of the profound scholarship of which it is the product and because it presents an excellent example of how near to each other, in discussion of this kind, dwell truth and error.

Third, if economic theory is such a simple and harmless sort of thing as I have represented it to be, the reader might wonder where the hostility comes from that has followed it ever since it attracted any attention at all (which was roughly since the time of the physiocrats) to this day. I shall simply list the main headings for an answer which our story will amply verify:

(1) At all times, including the present, in judging from the standpoint of the requirements of each period (not judging the state of the theory

---

[7] Hayek's teachers, the Austrian utility theorists, by operating the concept of marginal utility, actually discovered the calculus. It cannot be a crime to formulate their reasoning correctly.

as it was at any time by standards of a later time) the performance of economic theory has been below reasonable expectation and open to valid criticism.

(2) Unsatisfactory performance has always been and still is accompanied by unjustified claims, and especially by irresponsible applications to practical problems that were and are beyond the powers of the contemporaneous analytic apparatus.

(3) But while the performance of economic theory was never up to the mark, that is, never what it might have been, it was at the same time beyond the grasp of the majority of interested people who failed to understand it and resented any attempt at analytic refinement. Let us distinguish carefully the two different elements that enter into this resentment. On the one hand, there were always many economists who deplored the loss of all those masses of facts that actually are lost in any process that involves abstraction. So far as application is concerned, resentment of this type is very frequently quite justified. On the other hand, however, there are untheoretical minds who are unable to see any use in anything that does not directly bear upon practical problems. Or, to put it less inoffensively, who lack the scientific culture which is required in order to appreciate analytic refinement. It is very important for the reader to bear in mind this curious combination of justified and unjustified criticism of economic theory, which will be emphasized all along in this book. It accounts for the fact that criticism of economic theory practically always proceeded from both people who were above and people who were below the level of the economic theory of their time.

(4) The hostility that proceeded from these sources was frequently strengthened by the hostility to the political alliances which the majority of theorists persisted in forming. The classical example for this is the alliance of economic theory with the political liberalism of the nineteenth century. As we shall see, this alliance had the effect of turning for a time the defeat of political liberalism into a defeat of economic theory. And at that time many people positively hated economic theory because they thought it was just a device for bolstering up a political program of which they disapproved. This view came all the easier to them because economic theorists themselves shared their error and did all they could to harness their analytic apparatus into the service of their liberal political creed. In this and many analogous cases, of which modern economic theory is another deplorable example, economists indulged their strong propensity to dabble in politics, to peddle political recipes, to offer themselves as philosophers of economic life, and in doing so neglected the duty of stating explicitly the value judgments that they introduced into their reasoning.

(5) Although really implied under one or more of the preceding headings, we may just as well list as a separate one the view that economic theory consists in framing unfounded, speculative hypotheses in the first of the two meanings that were distinguished above. Hence, the tendency

quite frequent among economists or other social scientists to rule out economic theory from the realm of serious science. It is interesting to note that a propensity[8] of this kind is by no means confined to our field. Isaac Newton was a theorist if he was anything. Nevertheless, he displayed a marked hostility toward theory and especially toward framing of causal hypotheses. What he really meant was not theory or hypothesis of our second kind but just inadequately substantiated speculation. Perhaps there was also something else in this hostility, namely the aversion of the truly scientific mind to the use of the word 'cause' that carries a metaphysical flavor. Newton's example may also be appealed to in order to illustrate the truth that dislike of the use of metaphysical concepts in the realm of empirical science does not at all imply any dislike of metaphysics itself. [J. A. S. intended to have these nine paragraphs of indented material set in small type so that it would be easy for the average reader to skip them.]

[4. ECONOMIC SOCIOLOGY]

The reader will have observed that our three fundamental fields, economic history, statistics and statistical method, and economic theory, while essentially complementing each other, do not do so perfectly. In writing economic history, there are indeed statements that should not be added at all unless properly substantiated by pieces of reasoning that belong to economic theory: such a statement is, for instance, the one that links England's great economic development from the 1840's to the end of the nineteenth century to the repeal of the Corn Laws and of practically every other kind of protection. The schemata of economic theory derive the institutional frameworks within which they are supposed to function from economic history, which alone can tell us what sort of society it was, or is, to which the theoretical schemata are to apply. Yet, it is not only economic history that renders this service to economic theory. It is easy to see that when we introduce the institution of private property or of free contracting or else a greater or smaller amount of government regulation, we are introducing social facts that are not simply economic history but are a sort of generalized or typified or stylized economic history. And this applies still more to the general forms of human behavior which we assume either in general or for certain social situations but not for others. Every economics textbook that does not confine itself to teaching technique in the most restricted sense of the word has such an institutional introduction that belongs to sociology rather than to economic history as such. Borrowing from German practice, we shall find it useful, therefore, to introduce a fourth fundamental field to complement the three others, although positive work in this field also leads us beyond mere economic analysis: the field that we shall call Economic Sociology (*Wirtschaftssoziologie*). To use a felicitous phrase: economic analysis deals with the questions how people behave at any time and what the economic effects are they produce by so behaving; economic sociology deals with the question how they came to behave as they do.[1] If we define human behavior widely enough so that it includes not only actions and motives and propensities but also the social institutions that are relevant to economic behavior such as government, property inheritance, contract, and so on, that phrase really tells us all we need. Of course, it should be observed that this distinction is one we make for our own purposes. It is not implied that this distinction has been made by the authors themselves whom we are going to encounter. The proof of any pudding is in the eating and hence I refrain from saying anything in its defense just now.

---

[8] There is nothing to wonder at in the fact that on this ground alone the word economic theory, as used by some fellow economists, in itself implies derogation. To some extent, however, this attitude is simply a consequence of the fact that our intellectual tastes and aptitudes differ and that we naturally practice in our research according to our preferences. It is merely human nature that we overrate the importance of our own types of research and underrate the importance of the types that appeal to others. Perhaps it is not too much to say that we should never do what we are doing, both in science and in other pursuits of life, if we did not do this.

[5. POLITICAL ECONOMY]

The sum total of the historical, statistical, and theoretical techniques that have been characterized above, together with the results they help to produce, we call (scientific) economics. This term is of relatively recent growth. A. Marshall's great treatise was the first to establish its use, from 1890 on, at least in England and the United States.[1] In the nineteenth century, the term commonly in use was Political Economy, though in some countries other terms competed with it in the first decades of that century. This unimportant matter will be attended to, as we go along, in the subsequent Parts. But it is just as well to note two points at once. First, political economy meant different things to different writers, and in some cases it meant what is now known as economic theory or 'pure' economics. A warning must therefore be issued right now that in order to interpret correctly what any given writer said about the scope and method of political economy, we must always make sure of the meaning he attached to this term—some propositions about those subjects that have outraged critics become perfectly harmless if this rule be borne in mind. Second, ever since our science or agglomeration of sciences was baptized political economy by a not very significant writer of the seventeenth century whose work owes an undeserved immortality to this fact, there has been the implicit or explicit suggestion that the exclusive concern of our science was with the economy of the state—though of course not only of the *polis*, the city-state of Greece—or, what is almost the same thing, with public policies of an economic nature. This suggestion, which was still more emphasized by the German term frequently used as a synonym of political economy, *Staats-*

---

[1] I believe that this phrase is due to Mr. Gerhard Colm.

[1] Later on, a parallel usage was introduced, though less firmly established, in Germany. The word was Social Economics, *Sozialökonomie*, and the man who did more than any other to assure some currency to it was Max Weber.

wissenschaft, implied of course an altogether too narrow conception of the scope of economics. Incidentally, it over-emphasized the largely meaningless distinction between economics and what is now called business economics. Let us therefore have it understood that we ourselves do not divorce the two and that all the facts and tools relevant to the analysis of the behavior of individual firms, past or present, come within our meaning of economics just as much as do the facts and tools relevant to the analysis of the behavior of governments, and therefore will have to be added to the contents of any narrower political economics of the past. We have, however, to notice a novel meaning of the term political economy that has asserted itself of late.

Some contemporaneous economists are of the opinion that modern economic theory (in our sense) hangs too much in the air and does not take sufficient account of the fact that no sensible application to practical questions or even to the analysis of given situations of an economy can be made of its results without reference to the historico-political framework within which they are to hold. This opinion is sometimes extended so as to imply criticism of any work that concentrates on the improvement of theoretical or statistical tools of analysis, and then it seems to me to mean nothing except a failure to realize the inexorable necessity of specialized work. But all the more justified is this opinion if it be formulated as it has been in the first sentence of this paragraph. In particular, an economics that includes an adequate analysis of government action and of the mechanisms and prevailing philosophies of political life is likely to be much more satisfactory to the beginner than an array of different sciences which he does not know how to co-ordinate—whereas, to his delight, he finds precisely what he seeks ready-made in Karl Marx. An economics of this type is sometimes presented under the title Political Economy. In partial recognition of the truth that seems to be contained in this program, we have set up our 'fourth fundamental field,' Economic Sociology.

Political Economy in the sense discussed in the preceding paragraph calls up still another meaning of the term, the one that occurs in a discussion of Systems of Political Economy. And this meaning in turn evokes, by association, the term Economic Thought. But it will be convenient to deal with these two concepts in Chapter 4. There we shall also try to clarify the relation of this History of Economic Analysis to any history of the systems of political economy and to any history of the thoughts on economic subjects that float in the public mind.

[6. APPLIED FIELDS]

Division of labor, in research as well as in teaching, has produced, in economics as elsewhere, an indefinite number of specialties that are usually described as 'applied fields.' In order to obtain a list of them (which does not claim to be complete) let us draw inspiration from the courses offered by the larger institutions of higher learning in the United States that teach economics.

In addition to general survey courses and courses in economic history, statistics, economic theory, and economic sociology,[1] we find, first, offerings in a group of fields which everyone considers part and parcel of 'general economics' and which receive separate treatment only in order to facilitate more intensive treatment of their subjects. Such are money and banking, business fluctuations (or cycles), foreign trade (international economic relations), and, occasionally, location. Second, we find a group of fields, such as accounting, actuarial science, and insurance, that, historically, have preserved altogether too much independence from general economics (which is slowly being surrendered in the case of accounting) but are useful or even indispensable for all or some economists, because they offer both instruments of economic analysis or opportunities for applying it—witness, for example, the subject of depreciation. Third, we find a group of standard fields that pivot on the old-established departments of public economic policy especially: agriculture,[2] labor, transportation and 'utilities,' the problems of manufacturing industry (and of *its* public control)—for which there is no generally accepted English name—and public finance ('fiscal policy'), to which most people will add (for the present) a number of other fields such as marketing ('commodity distribution') and social security (so far as not covered by insurance). Socialism and 'comparative economic systems' or again 'population' may stand for a fourth group, and the 'area studies' that have become so popular of late for a fifth. Inclusion of other fields or the subdivision of some of those that have been mentioned could swell impressively the number of passengers in what we have described as a big bus. But our list as it stands and the reader's general knowledge suffice to verify the three statements which it is relevant to our task to make.

First, there is evidently no permanence or logical order to this jumble of applied fields. Nor are there definite frontier lines to any of them. They appear or vanish, they increase or decrease in relative importance, and they overlap with one another as changing interests and methods dictate. And, as has been indicated already, this is as it should be. To undertake or to refrain from undertaking any interesting task out of respect for frontiers or tectonics would be the height of absurdity.

Second, *all* those special or applied fields, and not only the three that have been mentioned as constituents of our first group, are mixtures of facts and techniques that form what we have described as the four fundamental divisions of economic analysis in our sense. The mixtures differ greatly from one another because there are wide stretches of ground on which there is much less need or opportunity for elaborate statistical or theoretical tools than there is in others or even none at all, though the historical element can hardly ever be entirely neglected with impunity. In addition, the mixtures also differ for another reason: the specialist workers in the various fields are, individually and groupwise, very differently grounded in the fundamental fields, and so mix techniques in a manner that differs considerably from what their chosen specialties might be thought to require—a fact that we must keep in mind if we are to understand why economics is what it is. In principle, however, it is impossible to divorce any of the applied fields from the fundamental ones.

---

[1] Owing to the discredit that, for good reasons and bad, attaches to the word 'theory' in many minds, this word is occasionally replaced by the word 'analysis' which then carries a meaning that is more restricted than the one attached to it in this book. The field of economic sociology does not, so far as I am aware, appear under this title or separately, but topics belonging in it are treated in courses on history, theory, 'comparative economic systems,' the more institutionally oriented courses on labor, and in a number of others.

[2] The field of agriculture offers an interesting example of a department of economics that it is hardly possible to treat without a considerable command of agricultural technology. In principle, though mostly to a lesser extent, this is true also in other departments and, so far as this is so, there is no point in drawing any sharp line between, say, the economics of banking, marketing, or manufacturing industry and the corresponding 'technologies.'

But, third, such divorce is also impossible because the applied fields not only apply a stock of facts and techniques that lies ready for their use in general economics but also add to it. These fields may accumulate 'private' stocks of facts and methods that are of little or no use outside their boundaries. Beyond this, however, they have repeatedly developed accumulations of facts and conceptual schemata that should be recorded as contributions to general economic analysis, even though the appointed wardens of the latter have sometimes been slow to welcome them. Modern agricultural economics affords some examples, the fields of transportation and public finance afford others. It follows that we cannot confine ourselves to the history of 'general' economic analysis but shall have to keep an eye on developments in applied fields as best we can.

CHAPTER 3

Interlude II: [Contemporaneous Developments in Other Sciences]

[1. ECONOMICS AND SOCIOLOGY] 25
[2. LOGIC AND PSYCHOLOGY] 27
[3. ECONOMICS AND PHILOSOPHY] 28

FROM TIME TO TIME, we shall look up from our work in order to view a piece of intellectual scenery. Slightly less perfunctorily, we shall, for every one of our periods, register some contemporaneous developments in other sciences (in our sense of the term) that were relevant or might, for one reason or another, be expected to have been relevant to the development of our own. What has to be said now about this aspect of our exposition is so preponderantly concerned with 'philosophy' that I might as well have entitled this chapter: Economics and Philosophy. The rest will be disposed of in the two paragraphs that follow.

[1. ECONOMICS AND SOCIOLOGY]

After what has been said in the preceding chapter about the paramount importance for economic analysis of history—and all the sciences and branches of sciences that this term stands for [1]—and of statistics, it goes without saying that we must try to keep some contact with them; the reason why this will be done in a fragmentary manner is not that a more systematic treatment would not be desirable but that such treatment is impossible within the space at our disposal and within the limits of my own knowledge—and even if it were possible, it would drown our own story in an unfathomable ocean. Similarly, it goes without saying that we cannot afford, subject to the same restrictions, to neglect the developments of sociology. This term we shall use in the narrow sense in which it denotes a single though far from homogeneous science, namely the general analysis of social phenomena such as society, group, class, group relations, leadership, and the like. And we shall use the term in this sense throughout, that is, for developments that antedate by centuries the introduction of the word. In a wider sense it means the whole of many overlapping and unco-ordinated social sciences—which is the term we prefer and which includes, among other things, our own economics, jurisprudence, hierology, 'political science,' ecology, and descriptive ethics and aesthetics (in the sense of sociology of moral behavior patterns and of art). In the footnote below the kinds of relations that may make developments in these and other fields relevant to a history of economic analysis are illustrated by the example of jurisprudence.[2]

---

[1] Amplifying what has been said about this point, I want to point out that all the historical sciences and branches of sciences that specialization (mainly of philological competence to deal with particular bodies of material) has produced are to some extent relevant for us even where they do not treat of specifically economic facts. For instance, the Graeco-Roman civilization is the subject of research by three clearly distinguishable groups of scholars, namely historians proper, philologists, and jurists. All three of them deal with many things that do not concern us. But even when they do so they contribute to the cultural picture of that world which as a whole is not a matter of indifference to us; and even where they describe military history or the history of the arts, they use the same techniques that they use in describing economic or social events and institutions, so that there is no hard and fast frontier at which our interest could be definitely said to stop.

The closeness of some of these relations has been recognized by our setting up the 'fundamental field' of Economic Sociology in which neither economists nor sociologists can get very far without treading on one another's toes. But it does not follow *either* that the co-operation between the two groups has actually been particularly close or fertile; *or* that either of them would have got along better if there had been more co-operation. As regards the first point it is the fact that ever since the eighteenth century both groups have grown steadily apart until by now the modal economist and the modal sociologist know little and care less about what the other does, each preferring to use, respectively, a primitive sociology and a primitive economics of his own to accepting one another's professional results—a state of things that was and is not improved by mutual vituperation. As regards the second point it is by no means certain that closer co-operation, so often clamored for by laymen who expect great things from 'cross-fertilization' with a certainty untroubled by professional competence, would have been an unmixed blessing. For it could certainly not have brought *net* gains because there would have been some loss of that efficiency which is the result of strict or even narrow specialization. This holds even for the division of economics and of sociology (in the wider sense) into departments that have developed into what are, to all intents and purposes, semi-independent sciences. This is precisely why we prefer to speak of social sciences rather than to speak of sociology in the wider sense. As an eminent economist once observed, cross-fertilization might easily result in cross-sterilization. This does not affect what has been said about the necessity of following up, at least in a fragmentary fashion, the developments of all the 'neighboring fields' in this book. It was only to avoid a possible misunderstanding that I thought it necessary to write the last sentences.

---

[2] The science or sciences (in our sense) whose subjects consist of statutory or customary 'law,' of legal practice, and of legal techniques are relevant to a history of economic analysis, first of all, because, to a considerable extent, economists have been lawyers (or, as we prefer to say, jurists) who brought to bear the habits of the legal mind upon the analysis of economic phenomena. For instance, the sociological and economic systems of the scholastic doctors of the sixteenth century (the literature *de jure et justitia*) cannot be understood if we do not realize that they were primarily treatises on the political and economic law of the Catholic Church and that their technique was derived primarily from the old Roman law as adapted to the conditions of the time. Second, the legal framework of the economic process, and the shaping influence of either upon the other, are, to say the least, of considerable importance for economic analysis. Third, the historical roots of the concept of 'economic law' are in the purely legistic concept of 'natural law' (see below Part II, ch. 2). Fourth, certain nineteenth-century economists professed to have derived inspiration for a historical view of the economic process from a school of jurisprudence that called itself the 'historical school' and whose emergence and position must be understood more completely than economists usually do if the elements of truth and error in that view are to be disentangled. I take the opportunity to add that the sociological analysis of law as a social phenomenon is one thing; that the study of the techniques of legal practice—the sort of thing that is taught in American law schools—is quite another thing; and that historical jurisprudence is still another thing: so we must distinguish at least three different 'sciences' of the law that differ in material, tools, and aims and are cultivated (though there are overlappings) by different groups of workers, and similarly in the fields of religion, ethics, and aesthetics. Confusion becomes almost excusable under these circumstances and great battles about principles and 'methods' have been fought on issues (e.g., in the sciences of art) that clear themselves up automatically as soon as it is realized that the contestants aim at different targets.

[2. LOGIC AND PSYCHOLOGY]

For the rest we are particularly interested in logic and psychology. The former claims our attention because economists have made a not inconsiderable contribution to it but especially because of their propensity to dogmatize and to quarrel about 'method': economists who enjoy this sport are apt to be influenced by the writings of the logicians of their time which therefore, though more apparently than really, gain some influence, legitimate or otherwise, upon our work. As regards psychology, there is the view that came first to the fore in the eighteenth century, and hence has been sponsored intermittently, that economics like other social sciences deals with human behavior. Psychology is really the basis from which any social science must start and in terms of which all fundamental explanation must run. This view, which has been defended as strongly as it has been attacked, we shall denote by the term Psychologism. Actually, however, economists have never allowed their analysis to be influenced by the professional psychologists of their times, but have always framed for themselves such assumptions about psychical processes as they thought it desirable to make. On the one hand, we shall note this fact occasionally with surprise because there exist problems in economic analysis that might be attacked with advantage by methods worked out by psychologists. On the other hand, we must avoid a very natural delusion. If we use an assumption the contents of which seem to belong to a particular field, this does not necessarily mean that we actually invade that field. For instance, the so-called law of decreasing returns from land refers to what might be termed a physical fact. But, as has been pointed out already, this does not mean that in formulating this assumption we are entering the field of physics. Similarly, when I state the assumption that as I go on eating successive pieces of bread my desire for further such pieces decreases, I may be said to be stating a psychic fact. But, in doing so, I am not borrowing anything from professional psychology, good or bad; I am simply formulating what rightly or wrongly I believe to be a fact of common experience. If we place ourselves on this standpoint, we shall find that there is much less of psychology about economic propositions than one might think at first sight. To speak of psychological laws, such as the Keynesian law of the propensity to consume, is a flagrant abuse, because this practice suggests justification for our assumptions, which, in effect, do not exist. Nevertheless, it is necessary to glance occasionally at the developments in the field of professional psychology, and this necessity arises, though less often, also with respect to a number of other sciences. For the moment, we confine ourselves to mentioning biology as an example. There is, or has been, such a thing as social and economic Darwinism. If we are to appraise this phenomenon, it is just as well to make sure of what Charles Darwin actually said and of the methods and materials that induced him to say it.

[3. ECONOMICS AND PHILOSOPHY]

Now we turn to the subject of the relations between economics and philosophy. Or, to put it more precisely, to the question, how far economic analysis has experienced influences from philosophy.[1] Owing to the many meanings that have been assigned to the word philosophy, some care is needed in order to avoid confusion.

There is first a meaning for which our question is very easy to answer, or rather, for which no problem exists. The Greek 'philosopher,' who shaded off into the rhetor and sophist, was simply the man of intellectual pursuits. Taken in this sense, which was transmitted to the Middle Ages and survived right into the eighteenth century, philosophy meant the sum total of all scientific knowledge. It was simply the universal science, of which metaphysics formed a part not less than did physics, and physics not less than mathematics or any 'philosophy' on the nature of society and of the *polis*. This usage was bound to maintain itself so long as the stock, both of analytic tools and facts, remained small enough for one brain to encompass. More or less, this was the case until, very roughly, the middle of the eighteenth century, when the time of the polyhistors was definitely over.[2] As we have seen, St. Thomas Aquinas fell in with this use of the word philosophy, except that he excluded the sacred doctrine which was a science apart. All the others were 'philosophical disciplines.' It is interesting to note that St. Thomas made no attempt to assign to the former any other prerogative but that of super-mundane dignity and did not give it any authority over the latter.

---

[1] For reasons that will appear presently, we shall not go into the large literature on this subject any more than we can help. For the moment, it is sufficient to mention the English standard work, James Bonar, *Philosophy and Political Economy* (1st ed., 1893; 3rd ed., 1922).

[2] Of these polyhistors, or universal scientists, Gottfried Wilhelm Leibniz (1646-1716) was perhaps the most famous. His thought ranged from pure mathematics to political economy and back again to physics and to the metaphysical speculation of his monadology. His views on economics that have been collected with loving care by W. Roscher are too insignificant to be mentioned again. But Giambattista Vico (1668-1744) was a sociologist of outstanding importance, and in advertising for pupils he promised to teach everything that is knowable (*tutto lo scibile*). And never forget: Adam Smith wrote—and brilliantly—on the development of astronomy. It is true, of course, that many or most polyhistors excluded certain specialties from their universal competence. Thus, most of the great historians were nothing but historians; most of the great physi-

When we look over those comprehensive systems[3] of science, we cannot fail to make a discovery of the utmost importance for the problem in hand. Neither Aristotle nor any of the later polyhistors succeeded in unifying, or even attempted to unify, the various departments of his teaching and, in particular, to assert in each of them his views on the 'last causes,' the 'ultimate meaning' of things, and the like. The physical theories of Aristotle, for instance, are entirely independent of his views on those 'fundamentals' and could, so far as these are concerned, just as well have been different from what they were. And this is as true of his political sociology (for example, his investigations into the constitutions of Greek city-states) as it is of his physics. Similarly, Leibniz' views on foreign trade have nothing whatever to do with his fundamental vision of the physical and the moral world and he could, so far as these are concerned, just as well have been a free trader. Therefore, we had better speak of a compound of sciences rather than a universal science. This compound broke to pieces as the exigencies of the division of labor asserted themselves. It was then in the seventeenth and eighteenth centuries that philosophy was usually divided into natural and moral philosophy, a division that foreshadowed the German one between *Natur- und Geisteswissenschaften.*[4] There is another sense of the word philosophy in which no question arises of its influencing economics. This is the case if philosophy is conceived of as a science, like any other, that asks certain questions, uses certain materials, and produces certain results. Examples of the problems that arise, if we then define philosophy in this sense, would be: what is meant by matter, force, truth, sense perception, and so on. This conception of philosophy, which ap-

---

cians were nothing but physicians. The Greek philosophers kept aloof from the utilitarian ('banausic') arts.

[3] The reader is warned that the term System—which in fact carries no more a definite meaning than did its Greek prototype—is used in this book in a variety of different senses which should not be confused, for instance: a set of more or less co-ordinated principles of political action (e.g. liberal system, free-trade system); an organized body of doctrine (e.g. the scholastic system, Marshall's system); a set of quantities between which certain relations are assumed to exist (e.g. system of prices); a set of equations expressing such relations (e.g. the Walrasian system).

[4] For the sake of brevity we neglected a development that culminated around 1900 and produced philosophy in a sense that has some affinity with the sense in which philosophy simply means science in general: namely, the sense that makes philosophy an attempt to construct a consistent picture of the empirical world from the contributions made by the individual scientists. This conception will be mentioned in its place, but all that we need to say about it here is that it does not create any difficulty or problem concerning the relation between philosophy and economics. A philosophy in this sense evidently does not undertake to restrict the autonomy of any of the individual sciences.

peals to many who are not philosophers, makes philosophy completely neutral as regards any particular proposition in any other science. It comes near to making philosophy synonymous with epistemology, the general theory of knowledge.

But a problem, and a very important one, does arise if we define philosophy to mean all theological and non-theological systems of beliefs ('speculative systems') concerning ultimate truths (realities, causes), ultimate ends (or values), ultimate norms. Ethics and aesthetics enter into such systems, not as sciences of certain sets of phenomena (behavior patterns) which they seek to describe (explain) but as normative codes that carry extra-empirical sanctions.[5] One may well ask whether economics does not also enter in the sense that a writer's 'philosophy' determines, or is one of the factors which determine, his economics.

In order to prepare the ground for our answer I shall first mention a few illustrative cases from the history of other sciences. For any worker whose philosophy includes Christian belief, research is research into the works of God. For him, the dignity of his vocation flows from the conviction that his work is revealing a part, however small, of the Divine order of things. Thus, Newton expressed Christian beliefs in a purely scientific work. Leibniz went readily from matters of pure physics and mathematics to matters of theology—he evidently saw no difference of methodological principle between the two, and theological aspects suggested themselves to his mind with the utmost ease. Leonhard Euler (1707-83) argued for his 'method for finding curves that enjoy certain extremal properties' on the ground that the world is the work of the most perfect Creator and *hence* must be amenable to description in terms of maximum and minimum propositions. James P. Joule (1818-89), the co-discoverer of the fundamental principle of modern thermodynamics, the principle of the mechanical equivalent of heat, adduced the argument that, in the absence of the equivalence between heat and motion, something (energy) could be lost in the physical universe which it would be contrary to the dignity of God to assume. The last two instances might even be construed as proving direct influence of Euler's and Joule's beliefs upon their analytic work. Nevertheless nobody doubts that there was no influence of this kind, that is, (a) that the scientific work of the four authors mentioned was not deflected from its course by their theological convictions; (b) that it is compatible with *any* philosophical positions; and (c) that there would be no point in trying to explain its methods or results by their philosophical positions. They simply co-ordinated their methods and results with their live Christian belief as they would co-ordinate with it everything else they did. They put their scientific work in a theological garb. But, so far as the content of this work is concerned, the garb was removable.

---

[5] This also applies to materialism in its technical philosophical sense, that is, to the doctrine that has not changed from the days of Leucippus and Democritus to this day and holds that 'matter' is the ultimate reality and exists independently of experience. I take the opportunity offered by the need for an illustrative example of the text above to bring home to the reader that the word 'materialism' means many things that have nothing to do with the technical meaning just defined. The 'idealist' philosophy that turns around the proposition (equally devoid of meaning for me personally) that in the last analysis reality (or the 'world') is 'spirit' would have served both purposes equally well: it would have given an example of philosophy in the sense in which it raises a problem of influence upon economics; and it would have served as another example of a word of many meanings that are commonly confused, the word Ideal.

I hold that the garb of philosophy is removable also in the case of economics: economic analysis has not been shaped at any time by the philosophical opinions that economists happened to have, though it has frequently been vitiated by their political attitudes. But this thesis, as it stands, is open to so many misinterpretations that we must now spell it out carefully. The best method of doing so is to state explicitly what it does *not* involve.

First, it does not involve 'scientism' (see above ch. 2, sec. 3). That is, I am not arguing that because the philosophical or theological garb is removable from propositions belonging to the physical sciences, it must therefore also be removable from propositions belonging to the social sciences. Our examples have been presented merely in order to illustrate what I mean by saying that the theological or philosophical creeds of a scientific worker need not exert any definite influence upon his analytic work, but not in order to establish my thesis. So far as those examples go, it is still an open question whether or not it also applies to the sciences of human action.

Second, my thesis does not imply of course that human action itself and the psychic processes associated with it—motives or methods of reasoning, whether political or economic or of any other type—are uninfluenced by, or uncorrelated with, philosophical or religious or ethical convictions. It so happens that it is part of my own social psychology to hold that this correlation is far from perfect—a robber baron may have professed quite sincerely a creed of meekness and altruism—but this is an entirely different matter. We are now concerned with the propositions of the sciences of human behavior *about* this human behavior and are not questioning that religious or philosophical elements must indeed enter into any explanations *of* this behavior whenever they aim at completeness or realism. *And this also applies to the scientific economist's 'politics' and to any advice or recommendation he may tender with a view to influencing 'policies.'* All that our thesis involves is that it does not apply to his tools and 'theorems.'[6]

Third, my thesis does not involve reliance on general considerations about the logical autonomy of the economic proposition or theorem from philosophy. This would be still compatible with the latter's influences creeping into the procedures of analytic work in a logically illegitimate manner. It might indeed be made plausible that such propositions, as that towns frequently developed from meeting places of merchants, do not carry any particular philosophical connotation; or that such propositions, as that ordinary significance tests are useless in the case of correlation between time series, are valid alike for the deist and the atheist; or that propositions, such as that increase in the rate of remuneration of a factor of production may decrease its supply, are compatible with *any* philosophy and imposed by none. But I am not asking my readers to put their trust in any arguments of this kind, however convincing they may seem to some. At the moment I am not making any attempt to establish my thesis. I am only announcing it and explaining its meaning. The proof will be supplied in the subsequent Parts, when it will be shown that even those economists who held very definite philosophical views, such as Locke, Hume, Quesnay, and above all Marx, were *as a matter of fact* not influenced by them when doing their work of analysis.

---

[6] If the reader finds this a difficult distinction to make, I sympathize with him. It is in fact this relation between an economist's political preferences and his analysis and the relation of the former with his philosophy—particularly evident if we extend 'philosophy' to include the sum total of a man's views on what is 'fair,' 'just,' 'desirable,' and so on—which do prevent most economists from accepting the argument above, which is after all only simple common sense if correctly understood.

The reason why so much emphasis has been placed upon the thesis that philosophy in any technical sense of the term is constitutionally unable to influence economic analysis and actually has not influenced it, is that the opposite thesis is one of the most important sources of pseudo-explanations of the evolution of economic analysis. These pseudo-explanations have a strong appeal for many historians of economics who are primarily interested in philosophical aspects and therefore attach an undue weight to the references to such aspects which in fact abound in the literature and are not always easy to recognize for what they are—frills without importance that nevertheless obliterate the filiation of scientific ideas.

CHAPTER 4

The Sociology of Economics

1. Is the History of Economics a History of Ideologies? 34
    [(a) *Special Nature of 'Economic Laws'*] 34
    [(b) *The Marxian Exposition of Ideological Bias*] 35
    [(c) *How Does a History of Economic Analysis Differ from a History of Systems of Political Economy; from a History of Economic Thought?*] 38
    [(d) *The Scientific Process: Vision and Rules of Procedure*] 41

[The Chapter is unfinished. There is no treatment of the last two sections outlined at the beginning of the chapter, namely:

2. The Motive Forces of Scientific Endeavor and the Mechanisms of Scientific Development
3. The Personnel of Science in General and of Economics in Particular]

We have already referred to a department of science that we called the Science of Sciences (*Wissenschaftslehre*). This science, starting from logic and to some extent also from epistemology, treats of the general rules of procedure in use in the other individual sciences. But there is another science about science which is called the Sociology of Science (*Wissenssoziologie*) [1] and treats of science as a social phenomenon. That is, it analyzes the social factors and processes that produce the specifically scientific type of activity, condition its rate of development, determine its direction toward certain subjects rather than other equally possible ones, foster some methods of procedure in preference to others, set up the social mechanisms that account for success or failure of lines of research or individual performances, raise or depress the status and influence of scientists (in our sense) and their work, and so on. Our emphasis upon the fact that the workers in the fields of tooled knowledge are apt to form distinct vocational groups qualifies particularly well for conveying to the reader the reasons why, and the extent to which, science constitutes a proper subject of sociological research. Our interest in this subject is of course confined, primarily at least, to the topics that may usefully figure in an introduction to a history of economic analysis. Of these the problem of ideology is by far the most important and will be dealt with first (1): under a second heading we shall consider the motive forces of scientific endeavor and the mechanisms of scientific development (2); and finally we shall discuss some topics concerning the personnel of science in general and economics in particular (3).

---

[1] [J. A. S. left space for this note but did not write it. In *Capitalism, Socialism and Democracy* (New York, 1950), p. 11, he explains the term Sociology of Knowledge as follows: 'The German word is *Wissenssoziologie*, and the best names to mention are those of Max Scheler and Karl Mannheim. The latter's article on the subject in the German Dictionary of Sociology (*Handwörterbuch der Soziologie*) can serve as an introduction.']

1. Is the History of Economics a History of Ideologies?

[(a) *Special Nature of 'Economic Laws.'*] The historical or 'evolutionary' nature of the economic process unquestionably limits the scope of general concepts and of general relations between them ('economic laws') that economists may be able to formulate. There is indeed no sense in denying, a priori, as has been done sometimes, that any such concepts or relations can be formulated at all. In particular it is not necessary that the concepts we use in the study of social groups should be familiar to the members of these groups themselves: the fact, if it be a fact, that the concept of income was not familiar to the people of the Middle Ages before the fourteenth century is no reason for not using it in an analysis of their economy.[1] But it is true that 'economic laws' are much less stable than are the 'laws' of any physical science, that they work out differently in different institutional conditions, and that neglect of this fact has been responsible for many an aberration. It is also true that whenever we attempt to interpret human attitudes, especially attitudes of people far removed from us in time or culture, we risk misunderstanding them not only if we crudely substitute our own attitudes for theirs, but also if we do our best to penetrate into the working of their minds. All this is made much worse than it would be otherwise by the fact that the analyzing observer himself is the product of a given social environment—and of his particular location in this environment—that conditions him to see certain things rather than others, and to see them in a certain light. And even this is not all: environmental factors may even endow the observer with a subconscious craving to see things in a certain light. This brings us up to the problem of ideological bias in economic analysis.

Modern psychology and psychotherapy have made us familiar with a habit of our minds that we call rationalization.[2] This habit consists in comforting ourselves and impressing others by drawing a picture of ourselves, our motives, our friends, our enemies, our vocation, our church, our country, which may have more to do with what we like them to be than with what they are. The competitor who is more successful than we are ourselves is likely to owe his success to tricks that we despise. As likely as not, the leader of a party not our own is a charlatan. The beloved girl is an angel exempt from human frailties. The enemy country is the home of monsters, our own the home of wholly admirable heroes. And so on. The importance of this habit for the health and happiness of the normal mind is obvious [3] and so is the importance of a correct diagnosis of its verbal manifestations.

---

[1] Let me make this quite clear. Sociologists like Max Weber who stand for the interpretative method of social states or changes—that is, who believe that it is our main or sole business to try to understand what things meant to the people concerned—may easily drift into the position that the use of any concepts not familiar to the people under study involves the error of assuming that their minds functioned just like ours. Now this error may be involved but it need not be: using a concept that carries meaning for us but not to the people that we observe is one thing; postulating that the concept carried meaning also for the latter is another thing. We need not go to primitive tribes in order to illustrate this: if, in terms of concepts of our own, we formulate the conditions for maximizing profits, we need not assume that the businessman himself uses these concepts; our 'theory' is perfectly meaningful even if we know that he does not.

[2] 'Rationalization' in the sense I am about to explain must be carefully distinguished from other meanings of the same word, and especially these two: (1) We sometimes speak of rationalization when we mean action that aims at improving something, e.g. an industrial concern, to make it conform to standards of which consulting specialists approve. (2) In research work we sometimes speak of rationalization when we mean the

[(b) *The Marxian Exposition of Ideological Bias.*] Half a century before the full importance of this phenomenon was professionally recognized and put to use, Marx and Engels discovered it and used their discovery in their criticisms of the 'bourgeois' economics of their time. Marx realized that men's ideas or systems of ideas are not, as historiography is still prone to assume uncritically, the prime movers of the historical process, but form a 'superstructure' on more fundamental factors, as will be explained at the proper place in our narrative. Marx realized further that the ideas or systems of ideas that prevail at any given time in any given social group are, so far as they contain propositions about facts and inferences from facts, likely to be vitiated for exactly the same reasons that also vitiate a man's theories about his own individual behavior. That is to say, people's ideas are likely to glorify the interests and actions of the classes that are in a position to assert themselves and therefore are likely to draw or to imply pictures of them that may be seriously at variance with the truth. Thus, the medieval knights fancied themselves as protectors of the weak and defenders of the Christian faith, whereas their actual behavior and, still more, other factors that had produced and kept in existence the social structure of their world are bound to look very different to an observer of a different time and class. Such systems of ideas Marx called ideologies.[4] And his contention was that a large part of the economics of his time was nothing but the ideology of the industrial and commercial bourgeoisie. The value of this great contribution to our insight into the processes

---

attempt to link a set of empirical findings to some theoretical principle that is to explain them. Thus, we say that we rationalize observed business behavior by the principle of profit maximization. These meanings have nothing to do with the one under discussion.

[3] This seems to me the essential point about rationalizations: they supply a sort of self-defense for our psychic organisms and make many a life bearable that would not be so without them. Let me add, however, that there is also another side to them that accounts for their role in psychoanalytic practice.

[4] The term is of French origin and at first meant simply the analysis of ideas, especially with reference to Condillac's theory. Occasionally it seems to have been used in much the same sense as the term Moral Philosophy, i.e. as roughly equivalent to social science. In this sense it was used by Destutt de Tracy. Napoleon I also used it but in a different sense that carried a derogatory connotation: he described as *idéologues* those opponents of his government, such as Lafayette, whom he considered unrealistic dreamers.

of history and into the meaning of social science is impaired but not destroyed by three blemishes, which it is as well to notice at once.

First, while Marx was so much alive to the ideological character of systems of ideas with which he was not in sympathy, he was completely blind to the ideological elements present in his own. But the principle of interpretation involved in his concept of ideology is perfectly general. Obviously we cannot say: everywhere else is ideology;[5] we alone stand on the rock of absolute truth. Laborist ideologies are neither better nor worse than are any others.

Second, the Marxist analysis of ideological systems of thought reduces them to emulsions of class interests which are in turn defined in exclusively economic terms. According to Marx the ideologies of capitalist society are, to put it crudely, glorifications of the interests of what he styled the capitalist class, whose interests are made to turn on the hunt for pecuniary profits. Ideologies that do not glorify the behavior of capitalist man in business but something else, for instance the national character and behavior, must hence always be reducible, however indirectly, to those economic interests of the dominant class. This however is not implied in the principle of ideological interpretation but constitutes an additional and much more doubtful theory. The principle itself implies only two things: that ideologies are superstructures erected on, and produced by, the realities of the objective social structure below them; and that they tend to reflect these realities in a characteristically biased manner. Whether or not these realities can be completely described in purely economic terms is another question. Without entering upon it here, we merely record the fact that we are going to attach a much wider meaning to the concept of Ideological Influence. Social location undoubtedly is a powerful factor in shaping our *minds*. But this does not amount to saying that our minds are exclusively shaped by the economic elements in our class position or that, even so far as this is the case, they are exclusively shaped by a well-defined class or group *interest*.[6]

Third, Marx and especially the majority of his followers assumed too readily that statements which display ideological influence are ipso facto condemned thereby. But it cannot be emphasized too strongly that, like individual rationalizations, ideologies are not lies. It must be added that statements of fact that enter into them are not necessarily erroneous. The temptation is great to avail oneself of the opportunity to dispose at one stroke of a whole body of propositions one does not like, by the simple device of calling it an ideology. This device is no doubt very effective, as effective as are attacks upon an opponent's personal motives. But logically it is inadmissible. As pointed out already, explanation, however correct, of the reasons why a man says what he says tells us nothing about whether it is true or false. Similarly statements that proceed from an ideological background are open to suspicion, but they may still be perfectly valid. Both Galileo and his opponents may have been swayed by ideologies. That does not prevent us from saying that he was

---

[5] [J. A. S. put a pencil note 'delusion?' beside this reference to ideology and the one in the next to the last sentence in the paragraph above.]

[6] [This problem is touched upon at intervals throughout the *History*.]

'right.' But what logical warrant have we for saying so? Is there any means of locating, recognizing, and possibly eliminating the ideologically vitiated elements in economic analysis? And does enough remain when we have done so?

It will be understood that our answers, though illustrated by examples, will for the moment be provisional and that the validity or otherwise of the principles I am about to formulate can be judged only by their applications in this book as a whole. But before we embark upon this task we must clarify a preliminary matter.

Unfortunately we have to bar a fire escape by which some of the strongest exponents of the doctrine that economics, and in principle all science, is vitiated by ideological delusions have tried to escape from the apparently inevitable conclusion concerning the possibility 'of scientific truth.' Professor K. Mannheim taught that, though ideological delusion is the common fate of mankind, there are nevertheless 'detached intelligences,' floating freely in space, who enjoy the privilege of being exempt from this fate. Slightly more realistically, everyone is a victim of ideological delusion except the modern radical intellectual who stands indeed upon the rock of truth, the unbiased judge of all things human. Now, if anything can be called obvious in this field, it is the fact that this intellectual is just a bundle of prejudices that are in most cases held with all the force of sincere conviction. But this apart, we cannot follow Mannheim down his fire escape because we have fully accepted the doctrine of the ubiquity of ideological bias and therefore cannot see anything else in the belief of some groups in their freedom from it but a particularly vicious part of their own system of delusions.[7] Now we turn to our task.

First, ideological bias, as defined above by our amended version of the Marxist definition, is obviously not the only danger that threatens economic analysis. In particular there are two others that should be mentioned specifically because they are easily confused with ideological bias. One is possible tampering with facts or with rules of procedure by Special Pleaders. All we have to say about this has been said already: here I only wish to warn the reader that special pleading is not the same thing as ideologically vitiated analyzing. Another danger proceeds from the inveterate habit of economists to pass value judgments upon the processes they observe. An economist's value judgments often *reveal* his ideology but they *are not* his ideology: it is possible to pass value judgments upon irreproachably established facts and the relations between them, and it is possible to refrain from passing any value judgments upon facts that are seen in an ideologically deflected light. We are not going to discuss the problem of value judgments here. It will be more convenient to do so on other occasions, especially when I shall have to report upon a full-dress debate on the subject in Part IV, Chapter 4.[8]

---

[7] Some groups, like bureaucracies, are more given to this ideology, which among other things involves the clearly ideological denial of any group interest of their own or at least of its influence on the policies that they originate or assist in shaping. This may be used as a first example of the influence of ideologies upon analysis. For this ideology of bureaucracies is an important factor in the unscientific habit of economists of using a clearly ideological theory of the state that raises the latter into a superhuman agency for the public good and neglects all the facts about the realities of public administration that modern political science provides.

[(c) *How Does a History of Economic Analysis Differ from a History of Systems of Political Economy; from a History of Economic Thought?*] The distinction above between ideologically biased statements and value judgments should not, however, be interpreted as a denial of their affinity. This affinity is even the main reason why I think it important to distinguish this history of economics—economic analysis—from either a history of Systems of Political Economy or a history of Economic Thought. By a system of political economy I mean an exposition of a comprehensive set of economic policies that its author advocates on the strength of certain unifying (normative) principles such as the principles of economic liberalism, of socialism, and so on. Such systems do come within our range so far as they contain genuinely analytic work. For instance, A. Smith's *Wealth of Nations* was, in fact as in intention, a system of political economy in the sense just defined and as such it does not interest us. All the more does it interest us by virtue of the fact that A. Smith's political principles and recipes—his guarded advocacy of free trade and the rest—are but the cloak of a great analytic achievement. In other words, we are not so much interested in *what* he argued for as we are in *how* he argued and what tools of analysis he used in doing so. His political principles and recipes themselves (including ideology—revealing value judgments) were no doubt what mattered most to himself and to his readers and, furthermore, what accounts primarily for the success of his work with the public and, in this sense, for its proud position in the history of human thought. But I am prepared to surrender them all as mere formulations of the ideology of his epoch and country, without validity for any other.

The same applies to what we define as Economic Thought, that is, the sum total of all the opinions and desires concerning economic subjects, especially concerning public policy bearing upon these subjects that, at any given time and place, float in the public mind. Now the public mind is never an undifferentiated or homogeneous something but is the result of the division of the corresponding community into groups and classes of various natures. In other words, the public mind reflects more or less treacherously, and at some times more treacherously than at others, the class structure of the corresponding society and the group minds or attitudes that form in it. Since these group minds have different opportunities of asserting themselves and especially of leaving their marks upon the literature which comes under the observation of later generations, questions of interpretation arise that are always difficult and sometimes impossible to solve. The public mind of a time and place is in particular not only differentiated sectionally, but also according to the position and intelligence of the individuals that form the same horizontal or vertical section. It is one thing with politicians, another with the shopkeepers, farmers, and laborers that are 'represented' by these politicians. And it may be formulated into systems of political economy by writers who belong, or who attach themselves, to particular sections. On the other hand, it may border on, or overlap with, analytic work as it has often done in treatises written by members of the commercial or industrial bourgeoisie. So far as it does do the latter, it will of course be our task to pick out as best we can such analytic performances from the common run of verbalizations of the humors of the times that are unconnected with any effort to improve our conceptual apparatus, and hence without interest for us. However difficult it may be to carry out this program in any particular case, the distinction between different masses of thought which we are trying to draw is quite clear on principle.

---

[8] [Unfortunately, there is only an unfinished version of this chapter, written in 1943. It was one of the sections that J. A. S. had taken out to rewrite and amplify.]

It would, I suppose, be possible to write alongside a history of economic analysis another history of the popular views on economic subjects. By the same token it is possible to write a history of economic thought that traces out the historical change of attitudes, mentioning analytic performances in passing. Such a history would indeed display the close association that exists within the attitudes of the public mind in the sense defined, with the kind of problems that at any given time interest analysts and form the general attitude or spirit in which they approach their problems. Our own plan is exactly the opposite one. We shall, of course, never neglect the general environment of economic thought in which, at various times, analysts did their work. But these environments and their historical changes are never our main object of interest. They come in as favorable or inhibiting influences upon analytic work, which shall remain the hero throughout our play. In trying to disentangle analytic work from its popular background, even though this background incessantly asserts its influence, we shall make a discovery which it is just as well to notice at once.

The development of analytic work, however much disturbed it may have been by the interests and attitudes of the market place, displays a characteristic property which is completely absent from the historical development of economic thought in our sense and also from the historical succession of systems of political economy. This property may best be illustrated by an example: from the earliest times until today, analytic economists have been interested, more or less, in the analysis of the phenomenon that we call competitive price. When the modern student meets the phenomenon on an advanced level of his study, for instance in the books of Hicks or Samuelson, he is introduced to a number of concepts and problems that may seem to him difficult at first, and would certainly have been completely un-understandable to so relatively recent an author as John Stuart Mill. But the student will also discover before long that a new apparatus poses and solves problems for which the older authors could hardly have found answers even if they had been aware of them. This defines in a common-sense and at any rate a perfectly unambiguous manner, in what sense there has been 'scientific progress' between Mill and Samuelson. It is the same sense in which we may say that there has been technological progress in the extraction of teeth between the times of John Stuart Mill and our own.

Now our ability to speak of progress in these cases is obviously due to the fact that there is a widely accepted standard, confined, of course, to a group of professionals, that enables us to array different theories of competitive price in a series, each member of which can be unambiguously labeled superior to the preceding one. We further observe that this array is associated with the lapse of time, in the sense that the later theory of competitive price almost always holds higher rank in the array of analytic perfection: whenever this is not the case, it is possible to assign this fact to extra-analytic and, in this sense, disturbing influences. But while it is thus possible to speak of analytic progress and impossible to deny the facts that this word is to denote, there is nothing corresponding to this in the field of economic thought or even in any historical array of systems of political economy. For instance, there would be no sense in speaking of a superiority of Charlemagne's ideas on economic policy as revealed by his legislative and administrative actions over the economic ideas of, say, King Hammurabi; or of the general principles of policy revealed by the proclamations of the Stuart kings over those of Charlemagne; or of the declarations of policy that sometimes preface acts of Congress over those Stuart proclamations. We may of course sympathize with some of the interests favored in any of those cases rather than with the interests favored in others, and in this sense array such documents also in a scale of preference. But a place of any body of economic thought in any such array would differ according to the judge's value judgments, and for the rest we shall be left with our emotional or aesthetic preference for the various schemata of life that find expression in those documents. We should be very much in the same position if we were asked whether Gauguin or Titian was the greater painter. That is, the only sensible answer to such a question is that there is no meaning to it. And the same thing applies of course to all systems of political economy if we exclude from them technical excellences or deficiencies. We may, indeed, prefer the world of modern dictatorial socialism to the world of Adam Smith, or vice versa, but any such preference comes within the same category of subjective evaluation as does, to plagiarize Sombart, a man's preference for blondes over brunettes. In other words, there is no objective meaning to the term progress in matters of economic or any other policy because there is no valid standard for interpersonal comparisons. It should be superfluous to add that this argument seems to clarify satisfactorily the differences between historians of economics on this point. Some of them think of technical analysis and an increasing command of facts; these are quite right in speaking of scientific progress in our field. Others are speaking of the changing humors, themselves the product of changing social conditions, that produce changing opinions about policies and desirabilities; these are quite right in denying that there is such a thing as progress in our field. Either group may err only in overlooking that there is an aspect of man's thought on economic subjects other than the one they are considering exclusively. Only those err without qualification who either see in the development of economic analysis nothing but a reflex of the changing humors of the public mind, or else indulge in the enviable but childish belief that political attitudes are a function of nothing except progressive insights.

[(d) *The Scientific Process: Vision and Rules of Procedure.*] We are now ready to take the second step in our inquiry into the dangers of ideological bias, namely, to ask the question how far it threatens the validity of results in that narrower field that we have described as Economic Analysis. Some readers may think even that there is no second step to take: since we have already surrendered, as ideologically conditioned, all the systems of political economy, and since, in addition, we have recognized as ideologies the less completely systematized sets of opinions on economic subjects that, at any time and place, 'float in the public mind,' we seem in fact to have admitted all there is to admit. And those readers in particular whose primary interest is in the history of the ideas that shape or, at all events, are closely associated with policies or with people's ideas about what is to be considered as fair or desirable in the management of economic affairs and whose interest in the development of technical economic analysis is secondary only are quite likely to grant—perhaps with a shrug of the shoulders—that our box of tools may well be as far removed from the influence of ideologies as are the techniques of any other science. Unfortunately we cannot take this for granted. Let us therefore analyze the scientific process itself in order to see where ideological elements may enter it and what are our means of recognizing and perhaps eliminating them.

In practice we all start our own research from the work of our predecessors, that is, we hardly ever start from scratch. But suppose we did start from scratch, what are the steps we should have to take? Obviously, in order to be able to posit to ourselves any problems at all, we should first have to visualize a distinct set of coherent phenomena as a worth-while object of our analytic efforts. In other words, analytic effort is of necessity preceded by a preanalytic cognitive act that supplies the raw material for the analytic effort. In this book, this preanalytic cognitive act will be called Vision. It is interesting to note that vision of this kind not only must precede historically the emergence of analytic effort in any field but also may re-enter the history of every established science each time somebody teaches us to *see* things in a light of which the source is not to be found in the facts, methods, and results of the preexisting state of the science.

Let us illustrate this at once by an outstanding example from our own field and time. Critics and admirers of the scientific performance of the late Lord Keynes will agree to the statement that his *General Theory of Employment, Interest, and Money* (1936) was the outstanding success of the 1930's and that it dominated analytic work for a decade after its publication, to say the least. The *General Theory* presented an analytic apparatus which the author summed up in Chapter 18. If we follow his exposition step by step (see especially pp. 249-54) we observe that this apparatus had been designed in order to give convenient expression to certain facts of 'the world in which we live'—although, as Keynes himself emphasized, these facts are attributed to his fundamental schedules (propensity to consume, attitude to liquidity, and marginal efficiency of capital) as special characteristics and not as 'logically necessary' properties. This analytic pattern will be discussed in the proper place,[9] where it will also be shown that the special characteristics in question are the characteristics of England's aging capitalism as seen from the standpoint of an English intellectual. There can be no question of their having been established by antecedent factual research. They are 'plausibly ascribed to our [the English] world, on our general knowledge of contemporary human nature' (p. 250). This is not the place to discuss the merits or demerits of this conception. All that matters here and now is that it *is* a conception or vision in our sense, and that it antedated all the analytic efforts that Keynes and others bestowed upon it. The process stands out in this case with such unsurpassable clearness because we can read a formulation of the vision, as yet analytically unarmed, in a few brilliant pages of Keynes's *The Economic Consequences of the Peace* (1919). So far as this line of endeavor of a man of many interests was concerned, the whole period between 1919 and 1936 was then spent in attempts, first unsuccessful, then increasingly successful, at implementing the particular vision of the economic process of our time that was fixed in Keynes's mind by 1919 at latest. Other examples, from our field as well as from others, could be adduced in order to illustrate this 'way of our mind.' But it would hardly be possible to find a more telling one.

Analytic effort starts when we have conceived our vision of the set of phenomena that caught our interest, no matter whether this set lies in virgin soil or in land that had been cultivated before. The first task is to verbalize the vision or to conceptualize it in such a way that its elements take their places, with names attached to them that facilitate recognition and manipulation, in a more or less orderly schema or picture. But in doing so we almost automatically perform two other tasks. On the one hand, we assemble further facts in addition to those perceived already, and learn to distrust others that figured in the original vision; on the other hand, the very work of constructing the schema or picture will add further relations and concepts to, and in general also eliminate others from, the original stock. Factual work and 'theoretical' work, in an endless relation of give and take, naturally testing one another and setting new tasks for each other, will eventually produce *scientific models*, the provisional joint products of their interaction with the surviving elements of the original vision, to which increasingly more rigorous standards of consistency and adequacy will be applied. This is indeed a primitive but not, I think, misleading statement of the process by which we grind out what we call scientific propositions. Now it should be perfectly clear that there is a wide gate for ideology to enter into this process. In fact, it enters on the very ground floor, into the preanalytic cognitive act of which we have been speaking. Analytic work begins with *material* provided by our vision of things, and this vision is ideological almost by definition. It embodies the picture of things as we see them, and wherever there is any possible motive for wishing to see them in a given rather than another light, the way in which we see things can hardly be distinguished from the way in which we wish to see them. The more honest and naïve our vision is, the more dangerous is it to the eventual emergence of anything for which general validity can be claimed. The inference for the social sciences is obvious, and it is not even true that he who hates a social system will form an objectively more correct vision of it than he who loves it. For love distorts indeed, but hate distorts still more. Our only comfort is in the fact that there is a large number of phenomena that fail to affect our emotions one way or the other, and that therefore look to one man very much as they do to another. But we also observe that the rules of procedure that we apply in our analytic work are almost as much exempt from ideological influence as vision is subject to it. Passionate allegiance and passionate hatred may indeed tamper with these rules. In themselves these rules, many of which, moreover, are imposed upon us by the scientific practice in fields that are little or not at all affected by ideology, are pretty effective in showing up misuse. And, what is equally important, they tend to crush out ideologically conditioned error from the visions from which we start. It is their particular virtue, and they do so automatically and irrespective of the desires of the research worker. The new facts he is bound to accumulate impose themselves upon his schema. The new concepts and relations, which somebody else will formulate if he does not, must verify his ideologies or else destroy them. And if this process is allowed to work itself out completely, it will indeed not protect us from the emergence of new ideologies, but it will clear in the end the existing ones from error. It is true that in economics, and still more in other social sciences, this sphere of the strictly provable is limited in that there are always fringe ends of things that are matters of personal experience and impression from which it is practically impossible to drive ideology, or for that matter conscious dishonesty,[10] completely. The comfort we may take from our argument is therefore never complete. But it does cover most of the ground in the sense of narrowing the sphere of ideologically vitiated propositions considerably, that is, of narrowing it down and of making it always possible to locate the spots in which it may be active.

---

[9] See Part v, ch. 5. [This appraisal of Keynes's *General Theory* was apparently the last thing written for the *History of Economic Analysis*.]

[J. A. S. did not complete his introductory part and stopped at this point. The following three paragraphs were found untyped among the notes and manuscript of this Part.]

While it is hoped that the foregoing treatment of the ideology problem will help the reader understand the situation within which we have to work, and put him on his guard without imbuing him with a sterile pessimism concerning the 'objective validity' of our methods and results, it must be admitted that our answer to the problem, consisting as it does of a set of rules by which to locate, diagnose, and eliminate ideological delusion, cannot be made as simple and definite as can the usual glib assertion that the history of scientific economics is or is not a history of ideologies. We have had to make large concessions to the former view, concessions that challenge the scientific character of all those comprehensive philosophies of economic life—such as the Political Economy of Liberalism—which are, to many of us, the most interesting and most glamorous of the creations of economic thought. Worse than this, we have had to recognize, on the one hand, that although there exists a mechanism that tends to crush out ideologies automatically, this may be a time consuming process that meets with many resistances and, on the other hand, that we are never safe from the current intrusion of new ideologies to take the place of the vanishing older ones. Under these circumstances, examples that may do something toward teaching the use of our rules may usefully complement the discussion above. We shall arrange our example in four groups.

---

[10] The role of what above is meant by conscious dishonesty is greatly enhanced by the fact that many things that do amount to tampering with the effects of logic do not in our field necessarily present themselves as dishonesty to the man who practices such tampering. He may be so fundamentally convinced of the truths of what he is standing for that he would rather die than give new weight to contradicting facts or pieces of analysis. The first thing a man will do for his ideals is lie. Now we do not interpret this element in the case as we do when speaking of ideological bias, but of course it reinforces the baleful influence of the latter.

First, when we look at the contents of our box of theoretical or statistical tools, we discover many items that are, and are known to be, ideologically neutral. For instance, we find a concept that is called the marginal rate of substitution, which has, since about 1930, been increasingly used in the theory of value instead of the older concept, marginal utility. Those who accepted the former in preference to the latter, have done so for purely technical reasons that are completely irrelevant to any ideology of economic life, and, as a matter of fact, nobody has ever asserted the contrary. Similarly, the question whether or not the ordinary significance tests are applicable to the case of correlation between time series is a very important one for economic analysis. But it would be waste of time to investigate the arguments that have been used in establishing the negative answer for ideological bias, because it is clear from the outset that they are impervious to it by nature. The results that we produce by means of reasoning that makes use of such stainless steel concepts or theories may still be ideologically vitiated. But we can at least be sure that the ideological bias, if there be any, must be sought for among the other elements of our reasoning.

Second, there are tools or theories that, though they can be shown to be actually neutral, yet acquire a putative ideological importance because people erroneously believe that they are relevant to their ideologies. We have just noticed the unchallenged fact that the transition from the marginal utility theory of value to a theory of value based upon the concept of marginal rate of substitution was ideologically neutral in the sense that either can be shown to be equally compatible with any ideology whatsoever. But this was not so with the preceding phase of the development of the theory of value. Among the opponents of the marginal utility theory of value were the Marxist sponsors of a labor theory of value who believed—as did many marginal utility theorists also—that the choice between labor and marginal utility 'explanations' of economic value depends upon our vision of the economic process and is ideologically relevant. Specifically, the Marxist notion that value is congealed labor was the first link in what Marxists considered to be a proof that the source of all incomes except wages is exploitation. However, as will be shown in Part III, the ideology . . .

[J. A. S. had nearly finished Section 1 of Chapter 4 (Is the History of Economics a History of Ideologies?). For a further discussion of some of these problems, the reader is referred to the presidential address (by J. A. S.) before the American Economic Association, 'Science and Ideology,' *American Economic Review*, March 1949.

Chapter 4 was apparently to have been the last chapter of the introductory Part. There were to have been two more sections (2. The Motive Forces of Scientific Endeavor and the Mechanisms of Scientific Development, and 3. The Personnel of Science in General and of Economics in Particular). These subjects are discussed at intervals throughout the *History* (see Index under these headings) and in connection with the author's concept of 'schools.' About the Ricardians, for example, he said: 'Moreover, the group was a genuine school in our sense: there was one master, one doctrine, personal coherence; there was a core; there were zones of influence; there were fringe ends.'

A few preliminary paragraphs (probably dictated), which deal to some extent with the personnel of science, were found among the author's notes and are printed below.]

The reader will have no difficulty in perceiving the relation which exists between the definition of a science as a technique that develops in a social group professionally devoted to its cultivation and the ideological aspects of the methods and results that emerge from the 'scientific' activities of such a group. Evidently there must be a certain amount of cohesion between its members, at least when the group has attained a sufficiently definite existence, a corporative spirit that produces explicit or subconscious rules according to which the members recognize each other and admit certain individuals and exclude others. In noticing a few of the phenomena to which these facts give rise we shall complete the little that can be said here on the subject of the sociology of science.

If it be possible at all to imagine an individual who no matter for what reason embarks for himself and by himself upon the investigation of any of those sets of phenomena that have ever become the objects of scientific efforts, it should also be possible to realize a very simple yet very fundamental truth. Our individual must first recognize the phenomena on which he is going to work and he must recognize them as being somehow connected with one another and distinct from others. This recognition is a cognitive act. But it forms no part of the analytic work. On the contrary, it supplies the object or material on which analysis works and is therefore a prerequisite of it. The analytic work itself then consists of two different though inseparable activities. The one consists in conceptualizing the contents of the vision. By this we mean the fixing of its elements into precise concepts that receive labels or names in order to retain their identity, and in establishing relations (theorems or propositions) between them. The other consists in hunting for further empirical data (facts) with which we enrich and check the ones originally perceived. It stands to reason that these two activities are not independent of one another but that there must be an incessant give and take between them. Attempts at conceptualization invite the hunt for further facts and the new facts discovered must themselves be inserted and conceptualized In an endless sequence both activities improve, deepen, and correct the original vision and also each other's results. We do try at any given stage of our scientific endeavors to construct schemata or systems or models by which to describe as best we can the set of phenomena we are interested in, which are then developed 'deductively' or 'inductively.' But they are provisional by nature and are always relative to the stock of facts we command. This is indeed a very imperfect description of scientific procedure but it brings out a fact that will be emphasized again and again in these pages: there is not and there cannot be any fundamental opposition between 'theory' and 'fact finding,' let alone between deduction and induction. It will be one of our tasks to show why the appearance of such opposition has emerged nevertheless.

In practice, of course, no scientific worker ever goes through all the stages of the work beginning with an independent vision of his own. Intuitive perception of novel aspects is indeed never absent so long as a science is really alive. But vision of the kind that produces novel methods or propositions or else leads to the discovery of novel facts—which then enter the science in the form of new hypotheses or restrictions—only adds to and perhaps partly displaces existing scientific structures, the bulk of which is handed from generation to generation as a matter of course. And practically always it isn't society as whole or even a random collection of members that hands on the stock of scientific knowledge but a more or less definite group of professionals who teach the rising generations not only their methods and results but also their opinions about the direction and the means of further advance. In a majority of cases competence in doing scientific work cannot be acquired, or can be acquired only by individuals of quite exceptional originality and force, from any source other than the teaching of recognized professionals. Let us briefly glance at some of the consequences of this fact.

First of all, it should be observed that this social mechanism is tremendously labor saving. By means of it any beginner who follows the advice received and who does the work assigned to him acquires knowledge of facts, grasp of problems, mastery of methods with an economy of energy that should set the bulk of his force free for exploration of lands that lie beyond the boundary line at which the competence of the teacher ends. There should be no reasonable doubt about it, therefore, that primarily the social mechanism glanced at is not only favorable to the development of conceptual apparatus and to the accumulation of factual knowledge but even that it supplies the most potent motive power of what is usually referred to as scientific progress. Obviously, however, there is also another side to the medal. Teaching in any established science stereotypes the mind of the tyro and may stunt such originality as he may have. This has another and less obvious consequence. Owing to the resistance that an existing scientific structure offers, major changes in outlook and methods, at first retarded, then come about by way of revolution rather than of transformation and elements of the old structure that might be permanently valuable or at least have not yet had time to yield their full harvest of result are likely to be lost in the process. There is thus plenty of justification, just as there is for the resentments of the revolutionary, for the propensity of a certain type of mind to emphasize continuity and to defend old insights against new ones. Many examples of this will be noticed in this book.

Second, the fact that existing structures once established tend to persist accounts in the field of scientific endeavor as it does in others for a phenomenon that is not easy to explain, the phenomenon of 'generations.' Consider a population with constant age distribution in which moreover the number of people that enter scientific vocations are equal to the number of people who retire. A given profession, say the profession of scientific economists, would then also display a constant age distribution. It is no doubt possible to construct sub-groups whose outlooks and methods may be expected to develop and there is no problem whatever in the antagonism of these age groups that we might observe. But this is not the problem of scientific generations for we also observe that at any given time a majority of the people in all the age groups display certain similarities of attitude so that, for example, it is possible to speak of a generation of 1880-1900 and to contrast it with the generation of 1920-1940 although younger and older men presumably differed in the first period as much as they did in the second. There would be no point in this if change in methods and results proceeded at an even rate. In the case of economists one might be tempted to explain this phenomenon by the change in social and economic conditions and by the consequent change in the practical problems that attracted attention in the two periods. But we find the same phenomenon in sciences that work on invariant environments. It is precisely this which gives us the clue to the nature of the problem and at the same time to its solution. Problems and methods not only change because environments change. They also change in consequence of the [fact that the] analytic work that is embodied in a given structure of a science has a way of resisting change.

Third, the professionals that devote themselves to scientific work in a particular field and even all the professionals who devote themselves to scientific work in any field tend to become a sociological group. This means that they have other things in common besides the interest in scientific work or in a particular science per se. In most cases they teach the science which they are trying to bring up and to make their living by teaching. Naturally, this will tend to evolve a social and economic type. The group accepts or refuses to accept co-workers also for reasons other than their professional competence or incompetence. In economics this grouping took long to mature but when it did mature it acquired much greater importance than it did in physics. We shall see how in most countries writers on economic topics hail from all the sectors of society. There were indeed factors that made for grouping at an early time, the most important instance being the Catholic scholastic doctors, but all the rest consisted of types that came from anywhere in the scales of social rank or of income brackets. In England, this was so even in the first half of the nineteenth century. In such cases we must use the word profession with a proviso. In England there was at the time indeed a profession of economists in the sense that there were writers on economic topics who mutually recognized their professional competence. But later on the association of scientific work with teaching produced an economic profession in a fuller sense of the word and this economic profession developed attitudes to social and political questions that *were similar also for reasons other than similar scientific views*. This similarity of conditions of life and of social location produced similar philosophies of life and similar value judgments about social phenomena. It would be unnecessary to dwell on the consequences of this were it not for the fact that it was closely associated with the phenomenon of scientific schools. Since this concept will inevitably play a considerable role in our story we had better stay for a moment in order to investigate its meaning.

PART II

FROM THE BEGINNINGS TO THE FIRST CLASSICAL SITUATION

(TO ABOUT 1790)

CHAPTER 1

Graeco-Roman Economics

1. Plan of the Part 51
[2. From the Beginnings to Plato] 53
[3. Aristotle's Analytic Performance] 57
[4. On the Origin of the State, Private Property, and Slavery] 59
[5. Aristotle's 'Pure' Economics] 60

  (b) *Money* 62
  (c) *Interest* 64
[6. Greek Philosophy] 65
[7. The Contribution of the Romans] 66
  [(a) *Absence of Analytic Work*] 67
  [(b) *Importance of Roman Law*] 67
  [(c) *Writings on Agriculture*] 70
[8. Early Christian Thought] 71

1. Plan of the Part

It has been explained in Part i that no science, in the sense there defined, is ever founded or created by a single individual or group. Nor is it in general possible to assign any precise date to its 'birth.' The slow process by which economics, as we now call it, rose into recognized existence ran its course between the middle of the seventeenth and the end of the eighteenth centuries. However, a concept that has been introduced in Part i may help us to be somewhat more precise, at least so far as the exigencies of exposition are concerned: the concept of Classical Situations.[1] Such a classical situation emerged in the second half of the eighteenth century and no such classical situation had ever emerged before. Availing ourselves of this, we might be tempted to start somewhere between 1750 and 1800, perhaps with the peak success of that epoch, A. Smith's *Wealth of Nations* (1776). But every classical situation summarizes or consolidates the work—the really original work—that leads up to it, and cannot be understood by itself. Therefore, we shall try to cover in this Part, as best we can, the whole span of more than 2000 years that extends from 'beginnings' to about twenty years after the publication of the *Wealth of Nations*. This task is much facilitated by the further fact that, so far as the purposes of this history are concerned, many centuries within that span are blanks.

---

[1] [J. A. S. did not complete the sections of Part i in which he would have discussed his concept of Classical Situations (and the difficulties inherent in periodizing) with special reference to his reasons for arranging the subject matter of the history of economic analysis in the three main divisions covered by Parts ii, iii, and iv. The reader will, however, find references to these problems at intervals throughout this book, especially in Part iii, ch. 1 and again in Part iv, ch. 1.

As J. A. S. points out, the term classic in this book has three meanings which should be distinguished from one another. Formerly it referred to the economic literature of the period from Adam Smith to J. S. Mill. 'It retained this label until, at a time when the word "classic" had lost its eulogistic connotation and was beginning to stand for "obsolete," Lord Keynes used the word in order to denote the teaching of A. Marshall and his immediate followers (or simply, pre-Keynesian economics).' J. A. S. himself uses the term Classical Situation to describe the achievement of substantial agreement after a long period of struggle and controversy—the consolidation of the fresh and original work which went before. When he wishes to use the term classic in the first sense (Adam Smith to J. S. Mill), he puts it in quotes 'to prevent confusion' (Part iii, ch. 1, sec. 1).]

The classical situation of the second half of the eighteenth century was the result of a merger of two types of work that are sufficiently distinct to justify separate consideration.[2] There was the stock of factual knowledge and the conceptual apparatus that had slowly grown, during the centuries, in the studies of philosophers. And, semi-independent of this, there was a stock of facts and concepts that had been accumulated by men of practical affairs in the course of their discussions of current political issues. These two sources of nascent economics cannot be separated strictly. On the one hand, there were numerous intermediate cases that cannot be classified without cutting many a Gordian knot. On the other hand, right into the time of the physiocrats, the scholar's technique was so very simple that most of it was within the reach of ordinary common sense and easily rivaled by unlearned practitioners, whose writings, therefore, cannot be dismissed as irrelevant to our purpose: on the contrary, they frequently rose to what we call in this book the scientific level. Broadly, however, our distinction is valid all the same.

Let us recall our distinction between Economic Thought—the opinions on economic matters that prevail at any given time in any given society and belong to the province of economic history rather than to the province of the history of economics—and Economic Analysis—which is the result of scientific endeavor in our sense. The history of economic thought starts from the records of the national theocracies of antiquity whose economies presented phenomena that were not entirely dissimilar to our own, and problems which they managed in a spirit that was, in fundamentals, not so very dissimilar either. But the history of economic analysis begins only with the Greeks.

Ancient Egypt had a kind of planned economy that turned upon her irrigation system. The Assyrian and Babylonian theocracies had huge military and bureaucratic establishments and elaborate legal systems—of which the code of Hammurabi (about 2000 B.C.) is the earliest legislative monument; they pursued an activist foreign policy; also they developed monetary institutions to a high degree of perfection, and knew credit and banking. The sacred books of

[2] Like periodization, the setting up of such types is an expository device. Though certainly based upon provable facts, neither must be taken too seriously or else what is intended to be a help for the reader turns into a source of misconceptions. Periods and types are useful only so long as this is remembered.

Israel, especially the legislative portions of them, reveal perfect grasp of the practical economic problems of the Hebrew state. But there is no trace of analytic effort. More than anywhere else we might expect to find such traces in ancient China, the home of the oldest literary culture of which we know. We find in fact a highly developed public administration that dealt currently with agrarian, commercial, and financial problems. These problems are frequently touched upon, mainly from an ethical standpoint, in the remains of Chinese classical literature, for instance in the teaching of Kung Fu Tse (551-478 B.C.), who was himself at two stages of his life a practical administrator and reformer, and of Mêng Tzŭ (Mencius, 372-288 B.C., works trans. by L. A. Lyall, 1932), from whose works it is possible to compile a comprehensive system of economic policy. Moreover, there were methods of monetary management and of exchange control that seem to presuppose a certain amount of analysis. The phenomena incident to the recurrent inflations were no doubt observed and discussed by men much superior to us in cultural refinement. But no piece of reasoning on strictly economic topics has come down to us that can be called 'scientific' within our meaning of the term.[3]

The obvious inference is of course highly uncertain. There may have been analytic work, the records of which failed to survive. But there is reason to suppose that there was not much of it. We have seen before that commonsense knowledge, relative to scientific knowledge, goes much farther in the economic field than it does in almost any other. It is perfectly understandable, therefore, that economic questions, however important, took much longer in eliciting specifically scientific curiosity than did natural phenomena. Nature harbors secrets into which it is exciting to probe; economic life is the sum total of the most common and most drab experiences. Social problems interest the scholarly mind primarily from a philosophical and political standpoint; scientifically they do not at first appear very interesting or even to be 'problems' at all.

[2. From the Beginnings to Plato]

So far as we can tell, rudimentary economic analysis is a minor element—a very minor one—in the inheritance that has been left to us by our cultural ancestors, the ancient Greeks. Like their mathematics and geometry, their astronomy, mechanics, optics, their economics is the fountainhead of practically all further work. Unlike their performance in these fields, however, their economics failed to attain independent status or even a distinctive label: their *Oeconomicus* (οἶκος, house, and νόμος law or rule) meant only the practical wisdom of household management; the Aristotelian *Chrematistics* (χρῆμα, possession or wealth), which comes nearest to being such a label, refers mainly to the pecuniary aspects of business activity. They merged their pieces of economic reasoning with their general philosophy of state and society and rarely dealt with an economic topic for its own sake. This accounts, perhaps, for the fact that their achievement in this field was so modest, especially if compared with their resplendent achievements in others. Classic scholars as well as economists who rate it more highly think of that general philosophy and not of technical economics. Also they are prone to fall into the error of hailing as a discovery everything that suggests later developments, and of forgetting that, in economics as elsewhere, most statements of fundamental facts acquire importance only by the superstructures they are made to bear and are commonplace in the absence of such superstructures. Such as they were, the scientific splinters of Greek economic thought [1] that are accessible to us may be gleaned from the works of Plato (427-347 B.C.) and Aristotle (384-322 B.C.).

---

[3] See, however, E. D. Thomas, *Chinese Political Thought* (1927); S. Y. Ly, *Les grands courants de la pensée économique chinoise dans l'antiquité . . .* (1936); and Huan Chang Chen, *The Economic Principles of Confucius and His School* (1911).

Greek thought, even where most abstract, always revolved around the concrete problems of human life. These problems of life in turn always centered in the idea of the Hellenic city-state, the *polis*, which was to the Greek the only possible form of civilized existence. Thus, by virtue of a unique synthesis of elements that with us dwell in different worlds, the Greek philosopher was essentially a political philosopher: it was from the *polis* that he looked into the universe, and it was the universe—of thought as well as of all other human concerns—that he found reflected in the *polis*. The Sophists seem to have been the first to analyze this universe very much as we do now: they are, in fact, the forefathers of our own methods of thought, our logical positivism included. But Plato's aim was not analysis at all but extra-empirical visions of an ideal

---

[1] We are not concerned with economic conditions and with public opinion about them. But the reader can with little trouble get an instructive glimpse of both from G. M. Calhoun, *The Business Life of Ancient Athens* (1926). This book may also bring home to him, among other things, the curious affinity that exists between our own reactions to business practice and those of the ancient Greeks. The works of Greek poets and historians are relevant only from this standpoint and need not be considered here though some of the latter, especially Thucydides and Polybius, are of absorbing interest to any student of society. Nor is it necessary to discuss Xenophon, whose *Oeconomicus* is precisely the sort of treatise on household management that went under similar titles until the sixteenth century, and whose *Poroi*, a treatise on Attic public finance, is of course very interesting for the economic historian (as is also the pseudo-Xenophontic treatise on the Athenian commonwealth, the survivor of what may have been a large literature written mainly by opponents of the radical regimes in post-Periclean Athens). Among 'philosophers,' Plato and Aristotle are of such commanding importance that reference may be confined to them, in a sketch like this. The huge literature about them naturally pays but little—and sometimes dilettantic—attention to the topics that matter to us. The purposes of the general reader will be served adequately by the perusal of M. L. W. Laistner, *Greek Economics* (1923), which also contains translations of portions of representative works. See also Auguste Souchon, *Les Théories économiques dans la Grèce antique* (1898). It seems, however, impossible not to mention such classics as Fustel de Coulanges' *La Cité antique* (12th ed. of the English trans. by W. Small, 1921); T. Gomperz' *Griechische Denker* (trans. by Magnus and Berry, 1901-12), and U. von Wilamowitz-Moellendorp's *Staat und Gesellschaft der Griechen und der Römer* (2nd ed., 1923)—masterly pictures of the cultural backgrounds from which sprang, among so many more important things, also the beginnings of economic analysis.

polis or, if we prefer, the artistic creation of one. The picture he painted of the Perfect State in his *Politeia* (*The Republic*[2]) is no more analysis than a painter's rendering of a Venus is scientific anatomy. It goes without saying that on this plane the contrast between what is and what ought to be loses its meaning. The artistic quality of the *Politeia* and of the whole literature—mostly lost—of which the *Politeia* seems to have been the peak achievement is well brought out by the German term for it, *Staatsromane* (literally: state novels). In default of a satisfactory English synonym we must use the word Utopia. The reader presumably knows that more or less under the influence of the Platonic example, this type of literature again found favor in the Renaissance and then continued to be produced, sporadically, to the end of the nineteenth century.[3]

But analysis comes in after all. There is a relation between the painter's Venus and the facts described by scientific anatomy. Just as Plato's idea of 'horseness' obviously has something to do with the properties of observable horses, so his idea of the Perfect State is correlated with the material furnished by the observation of actual states. And there is no reason whatever to deny the analytic or scientific character—remember: we do not attach any complimentary meaning to either of these words—of such observations of facts or relations between facts as are enshrined, explicitly or by implication, in Plato's construction. Reasoning of an analytic nature is still more prominent in a later work, the *Nomoi* (Laws). But nowhere is it pursued as an end in itself. Consequently it does not go very far.

Plato's Perfect State was a City-State conceived for a small and, so far as possible, constant number of citizens. As stationary as its population was to be its wealth. All economic and non-economic activity was strictly regulated—warriors, farmers, artisans, and so on being organized in permanent castes, men and women being treated exactly alike. Government was entrusted to one of these castes, the caste of guardians or rulers who were to live together without individual property or family ties. The changes introduced in the *Nomoi* are considerable—chiefly they are compromises with reality—but they do not touch the fundamental principles involved. This is all we need for our purpose. Though Plato's influence is obvious in many communist schemes of later ages, there is little point in labeling him a communist or socialist or a forerunner of later communists or socialists. Creations of such force and splendor defy classification and must be understood in their uniqueness, if at all. The same objection precludes attempts to claim him as a fascist. But if we do insist on forcing him into a strait jacket of our own making, the fascist strait jacket seems to fit somewhat better than the communist one: Plato's 'constitution' does not exclude private property except on the highest level of the purest ideal; at the same time it enforces a strict regulation of individual life, including limitation of individual wealth and severe restrictions upon freedom of speech: it is essentially 'corporative'; and it recognizes the necessity of a *classe dirigente*—features that go far toward defining fascism.

---

[2] The standard English translation by B. Jowett includes introductory essays on Plato's life, writings, and philosophy, and an analysis of the work.

[3] The best interpretation of Greek *Staatsromane* that I know of—and one that is itself a work of art—is Edgar Salin's *Platon und die griechische Utopie* (1921). This literature naturally reflects the social movements of its time, a subject into which it is impossible to enter here. See Robert von Pöhlmann's *Geschichte der sozialen Frage und des Sozialismus in der antiken Welt* (1912).

The analytic background, such as it is, comes into view as soon as we ask the question: why this rigid stationarity? It is difficult not to answer (however pedestrian such an answer may sound to the true Platonist) that Plato made his ideal stationary because he disliked the chaotic changes of his time. His attitude to contemporaneous events was certainly negative. He hated the Sicilian *tyrannos* (though we must not translate this word by tyrant). He almost certainly despised the Athenian democracy. Yet he realized that tyranny grew out of democracy and was, in any case, the practical alternative to it. Democracy, in turn, he interpreted as the inevitable reaction to oligarchy, and this again he traced to inequality of wealth, the consequence, as he thought, of commercial enterprise (*Politeia* VIII). Change, economic change, was at the bottom of the development from oligarchy to democracy, from democracy to tyranny (of a popular leader), that was so little to his taste. Whatever we may think of Platonic stationarity as the remedy, is there not a piece of—almost Marxian—economico-sociological analysis behind that diagnosis?

We need not stay to consider the numerous economic topics that Plato touched upon incidentally. It will suffice to mention two examples. His caste system rests upon the perception of the necessity of some Division of Labor (*Politeia* II, 370). He elaborates on this eternal commonplace of economics with unusual care. If there is anything interesting in this, it is that he (and following him, Aristotle) puts the emphasis not upon the increase of efficiency that results from division of labor per se but upon the increase of efficiency that results from allowing everyone to specialize in what he is by nature best fitted for; this recognition of innate differences in abilities is worth mentioning because it was so completely lost later on. Again, Plato remarks in passing that money is a 'symbol' devised for the purpose of facilitating exchange (*Politeia* II, 371; Jowett translated σύμβολον by 'money-token'). Now such an occasional saying means very little and does not justify the attribution to Plato of any definite view on the nature of money. But it must be observed that his canons of monetary policy—his hostility to the use of gold and silver, for instance, or his idea of a domestic currency that would be useless abroad—actually do agree with the logical consequences of a theory according to which the value of money is on principle independent of the stuff it is made of. In view of this fact it seems to me that we are within our rights if we claim Plato as the first known sponsor of one of the two fundamental theories of money, just as Aristotle may be claimed as the first known sponsor of the other (sec. 5b below). It is highly unlikely, of course, that these theories originated with them, but it is certain that they taught them and that they attached exactly the same meaning to them as did the authors who again took them up from the late Middle Ages on. We may assume this with confidence because those authors display both Platonic and Aristotelian influences clearly enough. In fact, filiation can be strictly proved.

The dialogue *Eryxias*, which was not written by Plato but has been transmitted to us among his writings and contains nothing that clashes with any of his known opinions, is mentioned here because it is the only extant piece of work that is wholly devoted to an economic subject and indeed treats it for its own sake. Otherwise, the contents of the dialogue—substantially an inquiry into the nature of wealth, which is related to wants and carefully distinguished from money—do not present any great interest.

[3. ARISTOTLE'S ANALYTIC PERFORMANCE]

Aristotle's performance is quite different. It is not only that in his works Platonic glamour is conspicuous by its absence, and that instead we find (if such a thing may be said without offense of so great a figure) decorous, pedestrian, slightly mediocre, and more than slightly pompous common sense. Nor is it only that Aristotle much more than Plato—in any case, much more frankly than Plato—co-ordinated and discussed pre-existing opinions that prevailed in what must have been a copious literature. The essential difference is that an analytic *intention*, which may be said (in a sense) to have been absent from Plato's mind, was the prime mover of Aristotle's. This is clear from the logical structure of his arguments. It becomes still clearer when we observe his method of work: for instance, his political concepts and doctrines were drawn from an extensive collection he laboriously made of constitutions of Greek states. Of course, he also looked for the Best State,[1] which was to realize the Good Life, the *Summum Bonum*, and Justice. He also overflowed with value judgments for which he claimed absolute validity (as do we). He also gave normative form to his results (as do we). And finally he also went hortatory on Virtue and Vice (as we do not).[2] But, however important all this may have been to him and, for more than 2000 years, to all his readers, it does not concern us at all; as I have said already and shall use every opportunity to repeat again and again, all this affects the goals and motives of analysis but it does not affect its nature.[3]

[1] It is interesting to note that he, too, philosophized primarily about the Greek city-state which, in spite of the exploits of his illustrious tutee, was and remained for him the only form of life worthy of serious attention. That Alexander's stupendous experiment in political construction completely failed to stir his imagination and to set his mind working on the vast vistas opened up by that experiment is highly characteristic of the man.

[2] He therefore refused assent to the pleasure-and-pain doctrines about behavior that were gaining ground in the Greece of his day. But though he did not give a utilitarian definition of happiness, he placed the concept of happiness in the center of his social philosophy. Whoever does this has taken the decisive step and has committed the original sin: whether he then emphasizes virtue and vice or pleasure and pain is secondary—the way is smooth from the one to the other.

[3] If any doubt were possible concerning Aristotle's analytic intention, it would be removed by his programmatic statement: 'As in other departments of science, so in politics, the [given] compound [of phenomena] should always be resolved into the simple elements or least parts of the whole' (*Politics* I, 1). To be sure, the term 're-

But only a small part of his analytic performance is concerned with economic problems. His main work as well as his main interest, so far as social phenomena are concerned, was in the field we have decided to call economic sociology or rather it was in the field of political sociology to which he subordinated both economic sociology and technical economics. It is as a treatise or textbook on state and society that his *Politics* must be appraised. And his *Nicomachean Ethics*—a comprehensive treatise on human behavior presented from the normative angle—also deals so preponderantly with political man, with man in the city-state, that it should be considered as a companion volume to the *Politics*, making up together with the latter the first known systematic presentation of a unitary Social Science. The reader presumably knows that up to, say, the times of Hobbes, all that went under the name of political science and political philosophy fed upon the Aristotelian stock. For our purpose, it must suffice to note: (1) that not only was Aristotle, like a good analyst, very careful about his concepts but that he also co-ordinated his concepts into a *conceptual apparatus*, that is, into a system of tools of analysis that were related to one another and were meant to be used together, a priceless boon to later ages; (2) that, as is indeed implied in his 'inductive' approach alluded to above, he investigated processes of change as well as states; (3) that he tried to distinguish between features of social organisms or of behavior that exist by virtue of universal or inherent necessity (φύσει) and others that are instituted by legislative decision or custom (νόμῳ); (4) that he discussed social institutions in terms of purposes and of the advantages and disadvantages they seemed to him to present, and that he himself thus gave in, and led followers to give in, to a particular form of the rationalist error, namely, the teleological error.[4] Deferring consideration of his concept of Natural Law, we confine ourselves to three characteristic samples of his analysis.

---

solving' is but a literal equivalent to 'analyzing' and actually identifies only a particular type of the activity we mean to indicate by analysis. It is, however, the spirit of the passage that counts and not its particular wording. The passage as a whole clearly expresses the fact that Aristotle consciously applied an analytic method.

[4] Teleology, or the attempt to explain institutions and forms of behavior *causally* by the social need or purpose they are supposed to serve, is obviously not always erroneous: many things in society can be, of course, not only understood in terms of their purpose but also causally explained by it. In all sciences that deal with purposive human actions, teleology must always play some role. But it must be handled with care; and there is the ever-present danger of making improper use of it. Mostly, this improper use consists in exaggerating the extent to which men act, and shape the institutions under which they live, according to clearly perceived ends that they consciously wish to realize in the most rational way. This is why the teleological error may be called a particular instance of the wider category of rationalist errors. It is interesting to note, however, that Aristotle was quite free from the teleological error in matters outside of his social science. In *Physicae auscultationes* (II, 8) he recognized, for instance, that our teeth are adapted to chewing food, not because they were made for this purpose but, as he thought, because individuals who are by accident endowed with serviceable teeth have a better chance of surviving than those who have not. What a curious piece of Darwinism!

[4. ON THE ORIGIN OF THE STATE, PRIVATE PROPERTY, AND SLAVERY]

Contrary to a widespread impression, Aristotle did not accept Plato's idea that the state developed from the patriarchal family or *gens*. Neither did he fully accept the idea of a Social Contract which seems to have been current among Sophists, but it always hovered around his path. Occasionally, he even talked about an original covenant so that the idea came easily to any disciple of his. This is interesting for two reasons. First, in the seventeenth and eighteenth centuries the social contract became the centerpiece of a line of thought whose exponents would have greatly resented being called Aristotelians. Second, Aristotle's handling of this subject is characteristic of his general attitude toward ideas of the Sophists. Much in Aristotle is strongly suggestive of Sophist influences. Yet he consistently argued against them, or rather against the views that we know to have been held by them. Perhaps it is not difficult to explain such an attitude; it is by no means rare. In any case, however, we must not allow it to obliterate the fact that he absorbed some of their thought and that it was mainly through his works that some Sophist influences reached the Middle Ages.

In the second Book of the *Politics*, Aristotle discussed private property, communism, and the family, mainly by way of criticizing Plato, Phaleas, and Hippodamus. His criticism of Plato—the only one of the three whose text we can compare with the criticism—is strikingly unfair and, moreover, misconceives completely the nature and meaning of Plato's creation. But the arguments he adduced for private property and the family and against communism were all the more successful—they read almost exactly like the arguments of middle-class liberals of the nineteenth century.

Aristotle lived in a society and breathed the air of a civilization to which slavery was essential. However, he also lived in a time when this essential institution was under fire from social critics. In other words, slavery had become a problem. This problem Aristotle attempted to solve by positing a principle that was to serve both as an explanation and as a justification. It stated what he thought was an indubitable fact, the 'natural' inequality of men: by virtue of inborn quality, some men are predestined for subjection, others for rule. He saw the difficulty of identifying this proposition with the quite different one that the former class of men actually furnishes the slaves of real life, and that the latter class of men actually furnishes the masters of real life. But he eliminated this difficulty by admitting 'unnatural' and 'unjust' cases of slavery such as would arise from indiscriminate enslavement of (Hellenic) prisoners of war. Most of us will see in this theory a peerless example of ideological bias coupled with apologetic intention (as we know, the two do not necessarily coincide). All the more important is it to make quite clear precisely *what* it is that justifies this impression. Our dislike of the proposition that slavery is due to a congenital inferiority—of some sort—in the enslaved would certainly not justify it. Nor is it sufficient that Aristotle's theory involves several non sequiturs. This would establish faultiness of analysis but not ideological bias. At the same time, if the mistakes committed in an argument all point in the same direction and if this direction agrees with what we may conceive the analyst's ideology to be, we are probably within our rights in suspecting ideological bias. Even so, it is not the suspicion of bias but the proof of the mistakes that should motivate rejection.

[5. ARISTOTLE'S 'PURE' ECONOMICS]

Keeping these principles of interpretation in mind, we now turn to Aristotle's embryonic 'pure' economics, the elements of which are to be found mainly in *Politics*, I, 8-11, and in *Ethics*, V, 5. Nothing would be easier than to show that he was primarily concerned with the 'natural' and the 'just' as seen from the standpoint of his ideal of the good and virtuous life, and that the economic facts and relations between economic facts which he considered and evaluated appear in the light of the ideological preconceptions to be expected in a man who lived in, and wrote for, a cultivated leisure class, which held work and business pursuits in contempt and, of course, loved the farmer who fed it and hated the money lender who exploited it. These things are just as interesting but not more so than are the corresponding though different value judgments and ideologies of the modern intellectual. The points that really matter for us are these. Aristotle based his economic analysis squarely upon wants and their satisfactions. Starting from the economy of self-sufficient households, he then introduced division of labor, barter, and, as a means of overcoming the difficulties of direct barter, money—the error of confusing wealth with money duly coming in for stricture. There is no theory of 'distribution.' This—presumably the extract from a large literature that has been lost—constitutes the Greek bequest, so far as economic theory is concerned. We shall follow its fortunes right to A. Smith's *Wealth of Nations*, the first five chapters of which are but developments of the same line of reasoning. Let us therefore look at the bequest more closely.

(a) *Value*. Aristotle not only distinguished value in use and value in exchange as clearly as did any later writer but he also perceived that the latter phenomenon derives somehow from the former. But in itself this is not only common sense but also commonplace, and further than this he did not advance. His failure to do so was made good by the later scholastics, who are entitled to the credit for having developed the theory of price which he himself cannot be said to have had. It has been held that this was due to his preoccupation with the ethical problem of justice in pricing—'commutative' justice—which diverted his interest from the analytic problem of actual pricing. Nothing could be farther from the truth. Preoccupation with the ethics of pricing, as the example of the later scholastics suffices to show, is precisely one of the strongest motives a man can possibly have for analyzing actual market mechanisms. Several passages show, as a matter of fact, that Aristotle tried to do so and failed.[1] He considered, however, the case of Monopoly (*Politics*,

---

[1] The most characteristic of these passages occurs in *Ethics*, V (1133), which I interpret like this: 'As the farmer's labor compares with the shoemaker's labor, so

I, 11 and *Ethics*, v, 5), which he defined as it has been defined ever since, namely, as the position in a market of a Single Seller (μόνος, alone or standing alone; πωλεῖν, to sell).[2] He condemned it as 'unjust.'

These facts seem to yield the solution of a problem that has exercised some historians of the theory of value. Aristotle no doubt sought for a canon of justice in pricing, and he found it in the 'equivalence' of what a man gives and receives. Since both parties to an act of barter or sale must necessarily gain by it in the sense that they must prefer their economic situations after the act to the economic situations in which they found themselves before the act—or else they would not have any motive to perform it—there can be no equivalence between the 'subjective' or utility values of the goods exchanged or between the good and the money paid or received for it. And since Aristotle did not offer any theory of exchange value or price, those historians concluded that he must have had in mind some mysterious Objective or Absolute Value of things that is intrinsically inherent in them and independent of circumstances or human valuations or actions—a metaphysical entity most welcome to people with philosophical propensities and most distasteful to people of a more 'positive' type of mind. But surely this does not follow. Failure to explain exchange value is not failure to recognize it as a fact. And it is much more reasonable to assume that Aristotle simply thought of the exchange values of the market, as *expressed* in terms of money, rather than of some mysterious value substance *measured* by those exchange values. But does not this imply that he accepted the actual commodity prices as the standard of his commutative justice and thereby lost the means of pronouncing upon their justice or injustice? Not at all. We have seen that he condemned monopoly prices. It is not farfetched to equate, for Aristotle's purpose, monopoly prices with prices that some individual or group of individuals have set to their own advantage. Prices that are given to the individual and with which he cannot tamper, that is to say, the *competitive* prices that emerge in free market under normal conditions, do not come within the ban. And there is nothing strange in the conjecture that Aristotle may have taken normal competitive prices as standards of commutative justice or, more precisely, that he was prepared to accept as 'just' *any* transaction between individuals that was carried out at such prices—which is in fact what the scholastic doctors were to do explicitly. If this interpretation be correct, his concept of the just value of a commodity is indeed 'objective,' but only in the sense that no individual can alter it by his own action. Moreover, his just values were social values—expressive, as he almost certainly thought, of the community's evaluation of every commodity[3]—but only in the sense that they were the super-individual result of

---

the product of the farmer compares with the product of the shoemaker.' At least, I cannot get any other sense out of this passage. If I am right, then Aristotle was groping for some labor-cost theory of price which he was unable to state explicitly.

[2] Joan Robinson added the corresponding concept, Monopsony, the position in the market of a Single Buyer (ὀψωνεῖν, to buy).

[3] This idea kept on turning up throughout the ages. We also find it in J. B. Clark (see below, Part IV). But though it seems to have had a strong appeal for some minds,

the actions of a mass of reasonable men. In any case, they are nothing more metaphysical or absolute than quantities of commodities multiplied by their normal competitive prices. The reader will have no difficulty in perceiving that, if values are defined in this way, the Aristotelian requirement of commutative justice acquires a sound and perfectly simple meaning. It will be fulfilled by their equality in every act of exchange or sale: if *A* barters shoes for *B*'s loaves of bread, Aristotelian justice requires that the shoes equal the loaves when both are multiplied by their normal competitive prices; if *A* sells the shoes to *B* for money, the same rule will determine the amount of money he ought to get. Since, under the conditions envisaged, A would actually get this amount, we have before us an instructive instance of the relation which, with Aristotle himself and a host of followers, subsists between the logical and the normal ideal and between the 'natural' and the 'just.'

We have expended such care on this argument because it disposes once for all of metaphysical speculations about objective or absolute value wheresoever and whensoever they might occur. Dismissing for good what we have seen to be a spurious problem, we shall henceforth understand by objective value of a commodity the magnitude defined and nothing else. Similarly, we shall not bother about any possible metaphysical meaning of the concept of Intrinsic Value since it is always possible (and in most cases very easy) to attach to it an entirely unmetaphysical one—as, for instance, in the most important case, where an author speaks of the intrinsic value of a coin.

(b) *Money*. The theory of money that Aristotle sponsored in conscious opposition, so it seems to me, to the alternative one sponsored by Plato was this: the very existence of any non-communist society involves the exchange of goods and services; this exchange, at first, 'naturally' takes the form of barter; but the people who want what other people have may not have what the latter want; therefore it will often be necessary to accept in exchange what one does not want in order to get what one does want by means of a further act of barter (indirect exchange); obvious convenience will then induce people to choose, tacitly or through legislative action, one commodity—Aristotle did not consider the possibility that people might choose more than one—as a Medium of Exchange. Aristotle briefly mentioned the fact that some commodities—such as the metals—are better fitted for this role than others, thus foreshadowing some of the tritest passages in nineteenth-century textbooks about homogeneity, divisibility, portability, relative stability of value,[4] and so on. Moreover, the requirements of his rule of equivalence in exchange naturally led him to observe that the Medium of Exchange will also be used as a Measure of Value. And finally he recognized, implicitly at least, its use as a Store of Value. Three of the four functions of money traditionally listed in those nineteenth-century

---

there is very little to it: there is no realistic sense in which it can be averred that any non socialist society as such evaluates commodities, though it is true of course that social influences shape the subjective valuations of individuals that govern their behavior and thus produce prices and 'objective values.'

[4] He recognized, however, that the value of gold and silver was not immutable.

textbooks—the fourth is to serve as the Standard of Deferred Payments—can therefore be traced to Aristotle.

Essentially, this theory embodies two propositions. The first is that, whatever other purposes money may come to serve, its fundamental function, which defines it and accounts for its existence, is to serve as a medium of exchange. Therefore, this theory belongs to what Professor von Mises has described as 'catallactic' theories of money (καταλλάττειν, to exchange). The second proposition is that in order to serve as a medium of exchange in the markets of commodities, money itself must be one of these commodities. That is to say, it must be a thing that is useful and has exchange value independently of its monetary function—this is all that intrinsic value means in this connection—a value that can be compared with other values. Thus the money commodity goes by weight and quality as do other commodities: for convenience people may decide to put a stamp on it (χαρακτήρ) in order to save the trouble of having to weigh it every time, but this stamp only declares and guarantees the quantity and quality of the commodity contained in a coin and is not the cause of its value. This proposition, which, of course, is not either identical with the first or implied by it, will identify what we shall henceforth call Metallism or the Metallist Theory of Money in contrast to the Cartal Theory of which Plato's is an example.[5]

Whatever may be its shortcomings, this theory, though never unchallenged, prevailed substantially to the end of the nineteenth century and even beyond. It is the basis of the bulk of all analytic work in the field of money. Therefore, we have every motive to make sure of our interpretation of Aristotle, whose personal influence in this matter is recognizable at least as late as A. Smith. No passage in the *Politics* will bear any other interpretation unless we attribute to Aristotle certain views that he mentioned but clearly attributed to others. But in the *Ethics*, playing upon the Greek word for current coin (νόμισμα), he did state that money exists not by 'nature' but by convention or legislation (νόμῳ), which seems to point in another direction. The fact, however, that he added, by way of explaining his meaning, that money might be changed or demonetized by the community suggests that he meant no more than that convention or legislation decides the material to be used for coining money and on the particular form to be given to the coins.[6]

Attention should finally be called to an interesting point of method. Aristotle's theory of money is a theory in the ordinary sense of this term, that is to say, an attempt to explain what money is and what money does. But, he presented it in a genetic form, as was his habit in dealing with any social institution: he lets money develop in what purports to be a historical sequence that starts from a condition or 'stage' in which there was no money. Of course, we need not see more in this than an expository device. In fact, the reader should remember this possible interpretation, which will redeem from sheer absurdity many an argument that presents itself in the garb of purely imaginary 'history,' as do, for instance, those theories of the state that use the idea of an original social contract. Even A. Smith's 'early and rude state of society' may benefit from an interpretation that refuses to take it seriously. But the case of money is different because the Aristotelian theory of the *logical* origin of money may pass muster—at a push—as a verifiable theory of its *historical* origin. Such instances as the Semite shekel or the tea-money of Mongolian nomads suffice to show this. It is in such cases that our point of method arises. Is it valid procedure to trace as far back as we can the history of an institution in order to discover its essential or its simplest meanings? Clearly not. Primitive forms of existence are as a rule not more simple but more complex than later ones: the chieftain who is judge, priest, administrator, warrior all in one is evidently a more complex phenomenon than are any of his specialized successors of later times; the medieval manor is conceptually a more complex phenomenon than is the U.S. Steel Corporation. Logical and historical origins must, therefore, be kept distinct. But this distinction presents itself only in advanced stages of analysis. The unsophisticated analyst invariably confuses them.[7] This confusion is undoubtedly implied in Aristotle's theories of money and also of other social institutions. He bequeathed it to the whole line of thinkers that descends from him, the English utilitarians included. And it survived, in spots, until today.

---

[5] See ch. 6 of this Part.

[6] We cannot enter, as we should, into a discussion of other passages. It must suffice to say that, at worst, they weigh but lightly as against the clear implications of Aristotle's emphasis on the necessity that money should consist of a material that is a commodity in its own right. Either the phrase that money is ὑπάλλαγμα τῆς χρείας κατὰ συνθήκην (*Ethics*, v, 5, 11) means that money is a means of exchange [used] according to convention or else I do not understand it.

(c) *Interest.* The rest of Aristotle's 'pure' economics, *considered from our standpoint*, is hardly worth mentioning. Many, if not most, of the things that were to become problems for the economist of later times he took for granted in the spirit of prescientific common sense; and he passed his value judgments upon a reality large stretches of which he failed to explore at all. The chiefly agrarian income of the gentleman of his time evidently presented no problem to him; the free laborer was an anomaly in his slave economy and was disposed of perfunctorily; the artisan, except so far as the just price of his product was concerned, fared little better; the trader (and shipowner), the shopkeeper, the money lender were mainly considered with a view to the ethical and political appraisal of their activities and their gains,[8] neither of which seemed to call for explanatory analysis. There is nothing surprising or blameworthy in this. It is by slow degrees that the physical and social facts of the empirical universe enter the range of the analytic searchlight. In the beginnings of scientific analysis, the mass of the phenomena is left undisturbed in the compound of common-sense knowledge, and only chips of this mass arouse scientific curiosity and thereupon become 'problems.'

---

[7] It should be observed, however, that identification of historical and logical evolution does not necessarily involve confusion. But if it does not involve confusion then it requires *either* proof of coincidence in every particular case *or* acceptance of an evolutionary or 'emanatistic' logic, such as Hegel's.

[8] Observe: I am not arguing against Aristotle's ideal of life or against any particular value judgments of his. Still less am I arguing for glorification of economic activity. On the contrary, I applaud the philosopher for having refused to identify rational behavior with the hunt for wealth. All I want to establish is that Aristotle, who in political matters was so alive to the necessity of analyzing and fact finding as a preliminary to judging, never seems to have bothered about this preliminary in 'purely' economic matters except in the matters touching value, price, and money. For instance,

For Aristotle, interest was no such chip. He accepted the empirical fact of interest on money loans and saw no problem in it. He did not even classify loans according to the various purposes they are capable of serving and does not seem to have noticed that a loan that financed consumption is something very different from a loan that financed maritime trade (*foenus nauticum*). He condemned interest—which he equated to 'usury' in all cases—on the ground that there was no justification for money, a mere medium of exchange, to increase in going from hand to hand (which of course it does not do). But he never asked the question why interest was being paid all the same.[9] This question was first asked by the scholastic doctors. It is to them that the credit belongs of having been the first both to collect facts about interest and to develop the outlines of a theory of it. Aristotle himself had no theory of interest. In particular, he should not be hailed as the forerunner of the monetary interest theories of today. For though he linked up interest with money, this was not due to analytic effort but to the absence of it: analysis that eventually leads back to a preanalytic view, that earlier analysis seemed to have disproved, imparts a different meaning to it.

[6. GREEK PHILOSOPHY]

So far as economics in the technical sense is concerned, we do not lose anything by leaving Greek thought at this point. Unfortunately, we lose a lot in another respect. There is hardly an idea in the realm of philosophy that does not descend from Greek sources, and many of these ideas, while not directly relevant to economic analysis itself, are all the more relevant to the general attitude and spirit of the analyst, though, as I have been careful to point out, such background influences should not be overemphasized. The various post-Aristotelian schools in particular, such as the Skeptics, Stoics, Epicureans, and then the Neo-Platonists, all not only influenced the Roman eclectics such as Cicero and Seneca but also helped to shape directly medieval as well as more modern thought. It goes without saying, for instance, that the Stoic idea of a rational universe[1] governed by immutable laws reflects an atti-

---

the fundamental difference he finds between the trader's and the producer's gains is essentially preanalytic. This fact has nothing to do with the other fact that he disapproved of the former and approved of the latter.

[9] In order to make this point quite clear, let us compare Aristotle's attitude toward interest with that of Karl Marx, who condemned the phenomenon at least as strongly as did Aristotle. But the analytic problem of interest was all the more important to him.

[1] On the meaning to be assigned in this connection to the term rational, see below, ch. 2, sec. 5c.

tude of mind that is not without significance for us. We must be content, however, to cast a glance at the message of Epicurus (about 341-270 B.C.).[2]

Epicurean philosophy might serve as a standard example for the truth that what a set of ideas comes to mean in the course of time is but distantly related to what the originators meant to convey. Epicurus lived in the Hellenistic period that witnessed the rapid decay of the *polis*. Active life, to the Greek, had meant active participation in the administration and politics of the city-states. For a man of culture such a life was then no longer possible. And Epicurus', like many other people's, answer to the resulting ethical problem—the problem of what might be called spiritual unemployability of the refined mind—was to leave the world alone and to try to achieve detached serenity (*αταϱαξια*) by *understanding resignation*. The causes that produced this particular attitude—there is no good equivalent for the German *Lebensstimmung*—were historically unique and so is really that attitude itself—or has been until today. But three elements of Epicurus' system of thought kept on turning up in the later Middle Ages, in the Renaissance, and also later on. The first of these elements is his atomistic materialism that tallies with, and perhaps influenced, later mechanistic philosophies of the universe. The second is this: Epicurus' attitude to the social environment may indeed be described as a highly sublimated egocentric hedonism or eudaemonism; and though his hedonism and eudaemonism was something very different from the hedonism and eudaemonism of later ages and in particular defined pleasure and pain quite differently, there is still a connecting line that leads from Epicurus to Helvetius and Bentham. Bentham's boisterous and vulgar utilitarianism would no doubt have shocked the old sage. But, much as we may dislike associating them, we must call both of them hedonists in a wider sense. The third element is the social contract, of which Epicurus, though not the originator, was an important exponent. But the idea was handed to the philosophers of natural law, who adopted it in the seventeenth and eighteenth centuries, by their scholastic predecessors, and this fact does not point to Epicurus.

[7. THE CONTRIBUTION OF THE ROMANS]

Let us now consider the still smaller contribution of the Romans. The doctrine that practical need—and not, as I hold, the lure of intellectual adventure—is the prime mover of scientific endeavor can be put to the test in the case of ancient Rome. Even in the earliest time when Rome was substantially a community of peasants, there were economic problems of first-rate importance that produced violent class struggles. By the time of the first Punic War important commercial interests had developed. Toward the end of the Republic, trade, money and finance, colonial administration, the plight of Italian agriculture, the food supply of the capital, the growth of *latifundia*, slave labor, and so on all presented problems that, in an artificial political setup created by military conquest and by all the consequences of incessant warfare, might have fully employed a legion of economists. At the height of cultural achievement, at the epoch of Hadrian and Antoninus Pius, when many of those difficulties were temporarily in abeyance and peace and prosperity reigned for a time in the vast realm, its able rulers and the galaxy of brilliant generals and administrators around them could have made use of a brain trust. Yet there was nothing of the kind—nothing beyond the occasional utterance of groans about the empire's unfavorable balance of trade or about *latifundia perdidere Italiam*.[1]

---

[2] See C. Bailey, *Epicurus, the Extant Remains* (1926); W. Wallace, *Epicureanism* (1880).

[(a) *Absence of Analytic Work.*] But this is not difficult to understand. In the social structure of Rome, purely intellectual interests had no natural home. Though its complexity increased as time went on, we may, for our purpose, put the case in a nutshell by saying that there were the peasants, the urban *plebs* (including traders and artisans), and the slaves. And above them all, there was a 'society' that no doubt had its business stratum (more or less represented by the order of the *equites*) but consisted mainly of an aristocracy that, unlike the Athenian aristocracy in the times after Pericles, never retired into opposition to lead a life of refined leisure, but threw itself wholeheartedly into public affairs both civil and military. The *res publica* was the center of its existence and all its activity. With widening horizons and increasing refinement, it cultivated an interest in Greek philosophy and art and developed a (largely derivative) literature of its own. These things were touched upon lightly, however, and were definitely considered as pastimes, essentially nugatory in themselves. There was little steam left for serious work in any scientific field, as Cicero's (106-43 B.C.) representative writings are sufficient to show.[2] And this deficiency was not, and could not be, made up by encouraging foreigners and freedmen who were directed primarily toward utilitarian tasks.

Of course, a society of this structure was bound to be passionately interested in history, mainly its own history. This was in fact one of the two main outlets for such scientific curiosity as the Roman mind harbored. But this curiosity was characteristically confined to political and military history. Sociological and economic backgrounds were hastily sketched—such sketches occur even in Caesar—social upheavals were reported with the utmost economy of general considerations. The one great exception is Tacitus' (*c.* 55-120) *Germania.*

[(b) *Importance of Roman Law.*] The only other outlet was the law. In order to understand the nature of the Roman achievement in this field and the reason why, unlike other legal systems, the Roman law plays a role in the history of economic analysis, we must recall a few facts about it. The reader is familiar, perhaps, with the English division of legal material into common law and equity. A somewhat analogous division existed in ancient Rome. There was the old and formalistic civil law (*jus civile, jus quiritium*), which, however, unlike the English common law, applied only to the affairs of the citizens (*quirites*) who until A.D. 212 formed but a part of the free population of the empire. This civil law[3] was developed by 'interpretation' through the agency of a college of priests (*pontifices*) and also through the agency of an officer of state in charge of judicial administration (*praetor urbanus*). This additional legal material bears some similarity to the English law of equity. But the bulk of what, to some extent, may be likened to English equity grew from another root, namely, from the relations, commercial and other, between non-citizens (*peregrini*) or between citizens and non-citizens. The body of legal rules that applied to these was called *jus gentium*. Note that this term, as used in Roman times, has nothing to do with the meaning it began to acquire from the seventeenth century on, namely, the meaning of Law of Nations (*droit des gens, Völkerrecht*). Since this body of law was formulated, and largely created, by another officer of state, who was in charge of a separate department of public administration (*praetor peregrinus*), it was also, together with the legal rules formulated or created by the *praetor urbanus*, referred to as 'officers' law' (*jus honorarium*): every *praetor* codified and promulgated it for his year of office in his *edictum*. Of course, there was also a steady stream of special enactments of various types. Comprehensive codification or even compilation was not attempted before the fourth century, though those praetorian *edicta* were fused, and stereotyped in an enactment, in the reign of Hadrian. We have, however, a second-century textbook, the *Institutiones*, by a jurist whose given name (*praenomen*) was Gaius.

---

[1] This phrase—that the large landed estates were the cause of the decline of Italy—was the elder Pliny's (23-79). The very fact that he saw nothing but the obvious, and in particular that he failed to see that the *latifundia* were as much the consequence as they were the cause of that decline, in itself shows what sort of economics was deemed adequate by a very able and highly civilized Roman (though it was not worse than is our own popular economics).

[2] *De re publica* is the one to come nearest to our field. Yet there is in it very little that could interest the economist, apart of course from what it tells us, directly and indirectly, about the economic conditions of that epoch. That applies still more to the *Letters to Atticus.*

Anglo-American jurisprudence, that is to say, the sum total of the techniques of legal reasoning and of the general principles to be applied to individual cases, is largely the work of the superior courts, whose decisions together with the motivating arguments, as everyone knows, have an authority that approaches that of an enactment. In Rome, the same practical needs produced a similar achievement but in a different way. English and American judges of the highest ranks are professional lawyers and, in principle at least, very eminent lawyers—leaders of the legal profession of great personal authority. The Roman judges were laymen—like our jurors—who had to be told what the law was. And the practicing lawyers were also laymen except for a group of professional pleaders (*causidici*) who had not much standing. This deficiency was made up in a way for which there is no analogy. Men of position and leisure became interested in legal questions almost as a hobby (unless they taught; the first to lecture on jurisprudence was, so far as we know, M. Antistius Labeo; the first to establish a school, Masurius Sabinus, c. A.D. 30). And they were interested not so much in the individual cases as such as in the logical principles relevant for their solution. They did not plead or do any other kind of legal work except one: they gave opinions on points of law whenever consulted by parties or attorneys or judges. So great was their authority that it may well be compared to that of English judges. It was first officially recognized by Augustus, who granted to the more eminent of these 'jurists' a special privilege of giving such opinions, the *jus respondendi*. These opinions were little monographs which together with more comprehensive works (such as the commentaries *ad edictum*) piled up to an extensive literature of which the remains, most of them preserved in the extracts made for Justinian's *Corpus* (528-33),[4] have been the object of admiration ever since.

---

[3] The reader should *not* confuse Civil Law in this sense with Civil Law in the sense used by modern Anglo-American lawyers: in their parlance it simply means the whole of the Roman law preserved in the *Corpus juris civilis* (see next footnote), as developed by medieval and modern practice.

The reason we have for referring to this literature is its genuinely scientific character. Those jurists analyzed facts and produced principles that were not only normative but also, by implication at least, explanatory. They created a juristic logic that proved to be applicable to a wide variety of social patterns—indeed to any social pattern that recognizes private property and 'capitalist' commerce. So far as their facts were economic, their analysis was economic analysis. Unfortunately the scope of this analysis was strictly limited by the practical purposes they had in view, which is why their generalizations yielded legal principles but not also economic ones. Mainly, we owe to them definitions—for example, of price, money, of purchase and sale, of the various kinds of loans (*mutuum* and *commodatum*), of the two types of deposits (*regulare* and *irregulare*), and so on—which provided starting points for later analysis. But they did not go beyond these starting points. Any theorems—for example, about the behavior of prices or about the economic importance of the 'irregular' deposit that creates no obligation to return the individual things deposited but only the obligation to return 'as much of the same kind' (*tantun-*

---

[4] A word on that compilation may be welcome to some readers. In A.D. 528, the emperor Justinian appointed a committee of jurists, presided over by his minister of finance (*quaestor sacri palatii*), Tribonianus, in order to trim into a manageable shape the exuberant foliage of both enactments and legal literature. Apart from subsequent imperial statutes (*Novellae*), that were added to it, the *Corpus juris civilis*, as the compilation was called, contains first, the *Institutiones*, a textbook for beginners based upon that of Gaius; second, the *Digestae* or *Pandectae*, which consist of a mass of extracts or quotations from the works of those consulting jurists; third, the Codex, which reproduced all the imperial statutes that were still in force. We are interested only in the *Digestae*. Unfortunately, Justinian ordered the destruction of everything that was not included in them. But the committee had at least the sense to refrain from mutilating the fragments included. Thus, the *Digestae*, though invested with the force of law, do not contain pulverized gems—pulverized into paragraphs of a code of law—but the gems themselves, a unique method of codification. Let us bow to the greatest of the authors included: Julius Paulus, Celsus, Papinianus, Ulpianus, Modestinus, Africanus, and Salvius Julianus—the order expressing a personal scale of preference that I cannot expect everybody to share.

dem in genere)—would have been irrelevant digressions. It is therefore not quite correct to speak of an economic theory of the *Corpus juris* [5]—not, in any case, of an articulate one—though it may be said with truth that the Roman jurists, by clarifying concepts, did preliminary work.[6]

The importance of this work—and also of the training in clear thinking that everybody undergoes who studies the literature—is greatly enhanced by the curious fact that the law of the *Corpus juris* was again taught from the twelfth century on and that subsequently it recovered its authority with the courts of most European countries ('reception' of the Roman law). Now, to the end of the eighteenth century, most of the writers on economic questions were, if not businessmen, either clergymen or lawyers by profession: the scholarly training of these two types of economists was largely provided by the Roman and the canon law and so there was a natural avenue by which the concepts, the spirit, and even, perhaps, some mannerisms of the Roman jurists entered the field of economic analysis. Among these concepts was the fundamental one of Natural Law. Once more, however, we defer its consideration, as we did when we met it in Aristotle: it will be more convenient to give later on a connected account of its development.

[(c) *Writings on Agriculture.*] We now turn for a moment to a minor matter, the Roman writings on agriculture (*De re rustica*). This branch of economic literature that seems to have been cultivated rather extensively by the Romans is more interesting for the economic historian than it is for us. It dealt with the practical principles of farm or rather estate management but rarely touched upon questions that come within our province. For instance, the elder Cato's advice that the landowner should sell aging slaves before they become useless and that he should show himself as hard a taskmaster as possible when inspecting his estate is no doubt very revealing in many respects but it does not involve any economic analysis. Some of those writers, of whom only Varro and Columella need be mentioned, occasionally made some remarks that suggest later developments, such as that the most profitable use of a piece of land depends, among other things, upon its distance from the center of consumption. But it is as true in these cases as it is in others that the mere statement of facts that are known to us from common experience is of no scientific importance, unless they become the starting point of an analysis that distills from them more interesting results.[7]

---

[5] See, however, Paul Oertmann, *Die Volkswirtschaftslehre des Corpus juris civilis* (1891), which, though obsolete in parts, is still the standard work on the subject.

[6] One point may, however, be worth mentioning. Julius Paulus (1, *Dig.*, XVIII, 1) explained the nature of money much as had Aristotle (from the inconvenience of direct barter). The passage is quite straightforward and calls for no comment until he adds that the stamped material of which the money is made (*materia forma publica percussa*), *usum dominiumque* (this may be safely translated by purchasing power) *non tam ex substantia praebet quam ex quantitate.* This passage has puzzled many a commentator and was the subject of a controversy in the eighteenth century. It seems, in fact, to renounce the metallist theory clearly indicated in the preceding sentence. But I do not think that such an 'aside' should be taken very seriously. In addition, there is the word *quantitas*, which has induced some writers to credit Paulus with a quantity theory of money. But there is no indication in the passage of an *inverse* relation between the quantity of money and its purchasing power. Moreover, the word *quantitas* is much more likely to mean 'nominal value' than quantity. This was its meaning in the literature on money in the Middle Ages and in the sixteenth century. All that Paulus probably meant was that people, in handling money in everyday transactions, usually take a coin at its nominal value without any conscious thought of the commodity value of its materials.

[8. Early Christian Thought]

We do not leave the Graeco-Roman world when we now turn for a moment to the Christian thought of the first six centuries. After what has been said about the nature of our aims, it is obvious that there would be no point in looking for 'economics' in the sacred writings themselves. The opinions on economic subjects that we might find—such as that believers should sell what they have and give it to the poor, or that they should lend without expecting anything (possibly not even repayment) from it—are ideal imperatives that form part of a general scheme of life and express this general scheme and nothing else, least of all scientific propositions.

But neither is there anything for us to garner in the works of those great men who during these centuries laid the foundation of the Christian tradition. And this does call for a word of explanation. For we might expect that, so far as Christianity aimed at social reform, the movement should have motivated analysis in the way in which, for example, the socialist movement did in our own time. Yet there is nothing of the kind either in Clement of Alexandria (about 150-215) or in Tertullian (155-222) or in Cyprian (200-258) to mention a few of those who did concern themselves with the moral aspects of the economic phenomena around them. They preached against wanton luxury and irresponsible wealth, they enjoined charity and restraint in the use of worldly goods, but they did not analyze at all. Moreover, it would be quite absurd to suspect mercantilist theories behind Tertullian's advice to content oneself with the simple products of domestic agriculture and industry instead of craving for imported luxuries, or a theory of value behind his observation that abundance and rarity have something to do with price. The same is true of the Christian teachers of the subsequent period. They lacked nothing in refinement and did develop techniques of reasoning—that partly hailed from Greek philosophy and from the Roman law—for the subjects that seemed to them worth while. Yet neither Lactantius (260-340) nor Ambrosius (340-97) —who might have elaborated a little on his statement that the rich consider as their rightful property the *common goods of which they have possessed*

---

[7] M. Terentius Varro (116-27 B.C.) was a man of some eminence who, in his long life, turned out an almost incredible quantity of literature on all sorts of subjects. Among his extant remains are *Rerum rusticarum libri tres* in which the remark above occurs. Much less interesting is *De re rustica* by L. Junius Moderatus Columella (1st century A.D.), which deals mainly with the cultivation of vegetables, trees, flowers, and so on, and with the rearing of animals.

themselves—nor Chrysostomus (347-407) nor St. Augustine (354-430), the accomplished author of the *Civitas Dei* and of the *Confessiones*—whose very *obiter dicta* reveal analytic habits of mind—ever went into economic problems though they did go into the political problems of the Christian state.

The explanation seems to be this. Whatever our sociological diagnosis of the mundane aspects of early Christianity may be, it is clear that the Christian Church did not aim at social reform in any sense other than that of moral reform of individual behavior. At no time, even before its victory, which may be roughly dated from Constantine's Edict of Milan (313), did the Church attempt a frontal attack on the existing social system or on any of its more important institutions. It never promised economic paradise or, for that matter, any paradise this side of the grave. The How and Why of economic mechanisms were *then* of no interest either to its leaders or to its writers.

1. The Great Gap

The Eastern Empire survived the Western for another thousand years, kept going by the most interesting and most successful bureaucracy the world has ever seen. Many of the men who shaped policies in the offices of the Byzantine emperors were of the intellectual cream of their times. They dealt with a host of legal, monetary, commercial, agrarian, and fiscal problems. We cannot help feeling that they must have philosophized about them. If they did, however, the results have been lost. No piece of reasoning that would have to be mentioned here has been preserved.

In the Germanic states of the West, similar problems arose even before the time of Charlemagne, and we know fairly well from literary sources as well as from documents how they dealt with them. But Charlemagne's vast empire presented problems of internal administration and international economic relations that had been unknown to any Germanic ruler before him. Practical wisdom, however, not inferior to that of any other age, is all that his measures reflect. The historians and philosophers who adorned his court touched upon economic questions incidentally, if at all.[1] So far as our subject is concerned we may safely leap over 500 years to the epoch of St. Thomas Aquinas (1225-74), whose *Summa Theologica*[2] is in the history of thought what the south-western spire of the Cathedral of Chartres is in the history of architecture.

2. Feudalism and Scholasticism

St. Thomas' life extended over the crest of feudal civilization. This term suggests the idea of a particular type of warrior society, namely, of a society dominated by a warrior stratum that was organized, on the principle of vassalage, in a hierarchy of fief-endowed lords and knights. From the standpoint of this hierarchy of warriors, the old distinction between men of free status and men of unfree status had lost much of its original significance. What mattered was not whether a man was free or not, but whether he was a knight or not. Even the Emperor of the Holy Roman Empire of German Nationality—to use the official phrase—who was in theory recognized as the feudal overlord of all Christianity, primarily was, and felt himself to be, a knight; and even the unfree man was a knight as soon as he had got hold of a horse and arms and had learned how to use them—which was at first a very simple matter, though in St. Thomas' age it had become a highly skilled occupation. This warrior class enjoyed unrivaled power and prestige, and hence impressed the stamp of its own cultural pattern upon the civilization of feudal times.

The economic base of this social pyramid consisted of the dependent peasants and manorial craftsmen on whose work the warriors lived. We thus seem to behold what at first sight looks like a structural unit in the sense that the phrase Social Pyramid is indeed meant to convey. But this picture is quite unrealistic. Societies, with the possible exception of primitive tribes and full-fledged socialism, are never structural units, and half the problems they present arise from the fact that they are not. The society of feudal times cannot be described in terms of knights and peasants any more than the society of capitalist times can be described in terms of capitalists and proletarians. Roman industry, commerce, and finance had not been destroyed everywhere. Even where they had been destroyed or where they had never existed, they—and consequently classes of bourgeois character—had developed or developed again before St. Thomas' day. In many places these classes had outgrown the framework of the feudal organization and, helped by the fact that a well-fortified town was normally impregnable to the knights' arts of warfare, they had successfully challenged the rule of the feudal lords—the most conspicuous instance being the victorious resistance of the towns of Lombardy. As a historical reality, therefore, feudalism means the symbiosis of two essentially different and largely, though not wholly, antagonistic social systems.

---

[1] The reader will find an instructive description of the intellectual situation of these times in M. L. W. Laistner, *Thought and Letters in Western Europe*, A.D. *500 to 900* (1931).

[2] New edition: *S. Thomae Aquinatis, Doctoris Angelici, Summa Theologica, diligenter emendata de Rubeis, Billuart et Aliorum* (Taurini, 1932). The work, though unfinished, has acquired unrivaled authority in the course of the centuries. But it contains much that was revolutionary in St. Thomas' day, and shortly after his death a number of propositions were declared heretical, though only locally. The canonization of the author in 1323 marks the turning of the tide. It was not, however, until the sixteenth century that Catholic thought definitely rallied round his teaching. Pope Leo XIII's encyclical *Aeterni Patris* (1879) made it the official teaching of the Church.

But there was another factor of nonfeudal origin and character that the warrior class failed to absorb or to conquer, for us the most important of all, the Roman Catholic Church. We cannot enter into a discussion of the extremely intricate relations of the medieval Church with the feudal powers. The one essential point to grasp is that the Church was not simply an organ of feudal society but an organism distinct from feudal society that always remained a power in its own right. However closely allied with, or dependent upon, feudal kings and lords it may at times have been, however near it may have come to defeat and to being harnessed into the service of the warrior class, it never resigned its own authority and never became the instrument of that or any other class. Since the Church was always able not only to assert itself but also to wage successful war upon the feudal powers, this fact should be too obvious to require explicit statement, were it not that historiography, inspired by a popular version of Marxian sociology, may easily create the impression—to put it in the crudest possible way—that medieval thought was merely the ideology of a landholding warrior class, verbalized by its chaplains. This impression would be wrong not only from the standpoint of those who refuse to accept the Marxian sociology of ideas, but also from the standpoint of Marx himself, even if we chose to interpret the Catholic system of thought as an ideology, it would still remain the ideology of the clergy and never merge with that of the warrior class. It is important to keep this in mind because of the practically complete monopoly of learning that the Catholic Church enjoyed until the Renaissance. This monopoly was due primarily to the spiritual authority of the Church. But it was greatly reinforced by the conditions of those ages in which there was neither room nor security for professional scholars except within a convent. In consequence, almost all 'intellectuals' of those times were either monks or friars. Let us briefly consider some implications of this.

All those monks and friars spoke the same unclassical Latin; they heard the same Mass wherever they went; they were formed by an education that was the same in all countries; they professed the same system of fundamental beliefs; and they all acknowledged the supreme authority of the Pope, which was essentially international: their country was Christendom, their state was the Church. But this is not all. Their internationalizing influence was strengthened by the fact that feudal society itself was international. Not only the Pope's but also the Emperor's authority was international in principle and, to some varying degree, in fact. The old Roman Empire and that of Charlemagne were no mere reminiscences. People were familiar with the idea of a temporal as well as of a spiritual superstate. National divisions did not mean to them what they came to mean during the sixteenth century; nothing in the whole range of Dante's political ideas is so striking as is the complete absence of the nationalist angle. The result was the emergence of an essentially international civilization and an international republic of scholars that was no phrase but a living reality. St. Thomas was an Italian and John Duns Scotus was a Scotsman, but both taught in Paris and Cologne without encountering any of the difficulties that they would have encountered in the age of airplanes.

In fact as well as in principle, practically everybody who wished to do so was allowed to enter a monastic order and also to join the ranks of the secular clergy. But advancement within the Church was open to everybody in principle only, since the claims of members of warrior-class families in fact absorbed the greater part of bishoprics and abboteies. But the man without connection was never entirely excluded from the higher dignities, not even from the highest; and, what is much more important for us, he was not debarred from becoming an idea-shaping and policy-shaping 'keyman.' The regular clergy (the monks) and the friars supplied, as it were, the general staff of the Church. And in the monasteries men of all classes met on equal terms. Naturally, the intellectual atmosphere was often charged with social and political radicalism, though this was, of course, much more the case at some times than at others and much more with the friars than with the regular monks. In the literature that we are going to survey we get this radicalism in a highly rarefied form but we do get it.

But how can a radical—hence also critical—attitude of mind be imputed to a social group whose members were bound to obey the dictates of a supreme and absolute authority? This apparent paradox is easily resolved. The lives and the faith of the monks and friars were indeed subject to authority that was, in theory at least, absolute and spoke immutable truth. But beyond the sphere of discipline and fundamental religious belief—beyond the matters that were *de fide*—that authority did not undertake to direct their thought, nor did it prescribe results.[1] In particular, it had not, in general, any motive for doing so in the department of political and economic thought, that is to say, for compelling the clerical intellectuals to expound and defend or to represent as immutable any given temporal order of things. The Church was *judge* of all things human; conflict with temporal authority was an ever-present possibility and very often the actual fact; the monastic orders were important instruments of Papal authority: these were no reasons for preventing them from looking upon temporal institutions as historically mutable works of man. I am far from wishing to belittle the importance of Christian ideals and precepts per se. But we need not invoke them in order to realize that monastic subordination to authority in matters of faith and discipline was compatible with extensive freedom of opinion in all other matters. We must go even further. Not only did the monks' sociological location—outside, as it were, of the class structure—make for an attitude of detached criticism of many things; there also was a power behind them that was in a position to protect that freedom. So far as treatment of political and economic problems is concerned, the clerical intellectual of that age was not more but less exposed to interference from political authority and from 'pressure groups' than was the laical intellectual of later ages.

---

[1] Facts that apparently contradict this statement will be discussed later on.

The indictment that unquestioning acceptance of ecclesiastic authority invalidated the reasoning of those monastic scholars from a scientific standpoint is thus seen to be without foundation. We have, however, still to consider a particular form of it. The analytic nature of their reasoning has often been denied on the ground that their arguments can have been only arguments from authority: subject to the authority of the Pope as they were, they had no other method left of establishing or refuting a proposition than to adduce for or against it literary authorities recognized by that supreme authority. But this is not so. The point can be cleared up by a reference to St. Thomas. He taught indeed that authority was of decisive importance in matters involving Revelation—namely, the authority of those to whom the revelations had been made—but he also taught that in everything else (and this includes, of course, the whole field of economics) any argument from authority was 'extremely weak.'[2]

With the monopoly of learning went the monopoly of 'higher' teaching. In the schools that were founded from the seventh century on, by temporal and spiritual lords, it was clerics who taught the tatters of Graeco-Roman science as well as theology and philosophical doctrines of their own—great teachers like Abelard attracted students and caused, occasionally, a lot of trouble for the controlling authorities. In some cases from these schools, in others independently, the self-governing 'universities' developed in the twelfth and thirteenth centuries—incorporated associations[3] of either teachers, as in Paris, or students, as in Bologna, who before long grouped themselves into theological, philosophical, legal, and medical 'faculties.' At first, princes and bishops had no more to do with them than what was implied in the granting of corporative privileges and in religious supervision. Accordingly, the universities enjoyed a large measure of freedom and independence; they gave more scope to the individual teacher than do the mechanized universities of today; they were a meeting ground of all classes of society; and they were essentially international. But from the fourteenth century on, government foundations became increasingly frequent. Governments also acquired control of previously independent institutions. Eventually, this changed everything. Government influence not only made for the assertion of purely utilitarian aims but also for restriction of freedom, particularly, of course, in matters of political doctrine. But, precisely because of the power that stood behind the clerical teachers, the universities held their own fairly well until the religious split in the sixteenth century.

---

[2] 'Nam licet locus ab auctoritate quae fundatur super ratione humana, sit infirmissimus . . . ,' *Summa* 1, quaest. 1, art. 8, *ad secundum* Of course, the scholastics all quoted copiously, but so do we. They deferred to authority—where they agreed with it—more than we do because they emphasized co-operative rather than individual opinion and attached great importance to continuity of doctrine. But this is all.

[3] *Universitas* originally meant nothing but corporation. Many people enrolled merely for the sake of the legal privileges that membership in such a self-governing corporation entailed. The meaning of *universitas litterarum,* which we attach to the term University, is of later origin.

The opportunities offered by the universities naturally reinforced the old tendency of scholars to become teachers. And since the public was then as prone as it is now to overemphasize the teaching at the expense of the production of what is being taught, medieval men of science were and are usually referred to as Schoolmen or Scholastics (*doctores scholastici*). In order to disabuse himself of prevailing preconceptions, the reader had better see in these scholastic doctors simply college or university professors. St. Thomas, then, was a professor. His *Summa Theologica* was, as he informs us in the preface, conceived as a textbook for beginners (*incipientes*).

3. Scholasticism and Capitalism

The processes that eventually shattered the social world of St. Thomas Aquinas are usually summed up in the phrase Rise of Capitalism. Though infinitely complex, they yet admit of a description in terms of a few broad generalizations that are not too hopelessly wrong. Also, though there was of course no break anywhere, it is possible to date developments at least by centuries. Capitalist enterprise had not been absent before, but from the thirteenth century on it slowly began to attack the framework of feudal institutions that had for ages fettered but also sheltered the farmer and the artisan, and to evolve the contours of the economic pattern that still is, or until quite recently was, our own. By the end of the fifteenth century most of the phenomena that we are in the habit of associating with that vague word Capitalism had put in their appearance, including big business, stock and commodity speculation, and 'high finance,' to all of which people reacted much as we do ourselves.[1] Even then these phenomena were not all of them new. Truly unprecedented was only their absolute and relative importance.

The growth of capitalist enterprise, however, created not only new economic patterns and problems but also a new attitude toward all problems. The rise of the commercial, financial, and industrial bourgeoisie of course altered the structure of European society and in consequence its spirit or, if you prefer, its civilization. The most obvious point about this is that the bourgeoisie acquired power to assert its interests. Here was a class that saw business facts in a different light and from a different angle; a class, in short, that was *in* business, and therefore could never look at its problems with the aloofness of the schoolman. But this point is second in importance to another. As we have seen in the first part of this book, it is more essential to realize that quite irrespective of the assertion of his *interests*, the businessman, as his weight in the social structure increased, imparted to society an increasing dose of his *mind*, just as the knight had done before him. The particular mental habits generated by the work in the business office, the schema of values that emanates from it, and the attitude to public and private life that is characteristic of it, slowly spread in *all* classes and over *all* fields of human thought and action. Results burst forth in the epoch of cultural transformation that has been so curiously misnamed Renaissance.[2]

---

[1] Owing to the importance of the financial complement of capitalist production and trade, the development of the law and the practice of negotiable paper and of 'created' deposits afford perhaps the best indication we can have for dating the rise of capitalism. Around the Mediterranean both emerged in the course of the fourteenth century, though negotiability was not fully established before the sixteenth. See A. P. Usher, *The Early History of Deposit Banking in Mediterranean Europe* (1943), and R. de Roover, 'Money, Banking, and Credit in Medieval Bruges,' *Journal of Economic History*, Supplement, December 1942.

One of the most important of these results was the emergence of the laical intellectual,[3] and hence of laical science. We may distinguish developments of three different kinds. First, there always had been laical physicians and lawyers; but in the Renaissance they began to crowd out the clerical element. Second, starting from their professional needs and problems, laical artists and craftsmen —there was really no sociological distinction between them—began to develop a fund of tooled knowledge (for example, in anatomy, perspective, mechanics) that was an important source of modern science but grew up outside of scholastic university science: such a figure as Leonardo da Vinci will illustrate this point; and the figure of Galileo will illustrate another point, namely, how this kind of development produced the laical physicist. It had its analogue in economics: the businessman and civil servant, also starting like the artist-craftsman from his practical needs and problems, began to develop a fund of economic knowledge which will be surveyed in the next chapter. Third, there were the Humanists. Professionally, these were classical scholars. Their scientific work consisted in the critical editing, translation, and interpretation of the Greek and Latin texts that became available in the fifteenth and sixteenth centuries. But they loved to believe that a command of Greek and Latin would make a man competent in everything; and this together with their social location—also outside of the scholastic universities—turned these critics of texts into critics of men, manners, beliefs, and institutions, as well as into all-round *littérateurs*. They did not, however, contribute to technical economics. For us they are important only so far as they influenced the general intellectual atmosphere of their age.

---

[2] The 'revival' of the interest in the thought and art of ancient Greece and Rome was so powerful a factor in the intellectual life of those times only because ancient forms provided convenient vessels for new needs and meanings. The real cultural achievement of that period did not consist in reconditioning old heirlooms.

[3] The word 'laical' has been chosen after some hesitation. 'Secular' would not do because it derives another connotation from the distinction: secular clergy—regular clergy. 'Laymen's science' conflicts with our use of the term layman (a man not trained in scientific method). 'Laicist' conveys the idea of an antagonism to the Church (cf., for instance, the phrases 'laicist state' or 'laicism'). So 'laical' will have to serve in order to denote people or any activity (scientific or propagandist) of people who are not in holy orders. The noun shall be 'laics.' There is a more serious difficulty, however. On the one hand, the educational system of the Catholic Church proved so strong that many laical intellectuals continued to be shaped by it. Many of them retained habits of mind that did not differ essentially from those of the intellectuals in holy orders. On the other hand, an increasing number of the latter renounced allegiance to the scholastic system of thought as completely as any laic could have done: Erasmus of Rotterdam (1467-1536) affords an early instance. Our distinction though based upon a real difference is therefore not an easy one to handle. It is not simply a question of the cloth.

The Catholic Church had little reason to object to the laical physician or lawyer as such and actually did not object to them; it was the most liberal patron of the artist-craftsman, whose art in fact remained primarily religious for a long time to come; it employed humanists in the Papal chancery and elsewhere, and the Renaissance Popes and Cardinals, some of whom were distinguished humanists themselves, invariably encouraged humanistic studies. The conflict that arose nevertheless is therefore a problem. And diagnosis of its nature is not facilitated by painting the picture all in black and white. There is little if anything to the saga of a new light that had flashed upon the world and was bitterly fought by the powers of darkness, or of a new spirit of free inquiry that the henchmen of hidebound authoritarianism vainly tried to smother. Nor is our understanding of the conflict helped by mixing it up with the related but quite different phenomenon of the Reformation—the intellectual revolution and the religious revolution reinforced each other but their sources are not the same; they do not stand to each other in any simple relation of cause and effect.

There was no such thing as a New Spirit of Capitalism in the sense that people would have had to acquire a new way of thinking in order to be able to transform a feudal economic world into a wholly different capitalist one. So soon as we realize that pure Feudalism and pure Capitalism are equally unrealistic creations of our own mind, the problem of what it was that turned the one into the other vanishes completely.[4] The society of the feudal ages contained all the germs of the society of the capitalist age. These germs developed by slow degrees, each step teaching its lesson and producing another increment of capitalist methods and of capitalist 'spirit.' Similarly, there was no such thing as a New Spirit of Free Inquiry whose emergence would call for explanation. The scholastic science of the Middle Ages contained all the germs of the laical science of the Renaissance. And these germs developed slowly but steadily within the system of scholastic thought so that the laics of the sixteenth and seventeenth centuries continued rather than destroyed scholastic work. This applies even where it is most persistently denied. Even in the thirteenth century Albertus Magnus observed, Roger Bacon experimented and invented—he also insisted upon the need for more powerful mathematical methods—while Jordanus the Nemore theorized in an entirely 'modern' spirit.[5] Even the heliocentric system of astronomy was not simply a bomb thrown at the scholastic fortress from outside. It originated in the fortress. Nicolaus Cusanus (1401-64) was a cardinal. And Copernicus himself was a canon (though he did not actually take orders), a doctor of canon law, lived all his life in church circles, and Clement VII approved of his work and wished to see it published.[6]

---

[4] This problem is a typical instance of what may be termed Spurious Problems, that is to say, of those problems that the analyst himself creates by his own method of procedure. For purposes of abbreviated description, we construct abstract pictures of social 'systems' that we endow with a number of well-defined characteristics in order to contrast them sharply. This method of (logically) Ideal Types (discussed below) has, of course, its uses, though it inevitably involves distortion of the facts. But if, forgetting the methodological nature of these constructions, we put the 'ideal' Feudal Man face to face with the 'ideal' Capitalist Man, transition from the one to the other will present a problem that has, however, no counterpart in the sphere of historical fact. Unfortunately, Max Weber lent the weight of his great authority to a way of thinking that has no other basis than a misuse of the method of Ideal Types. Accordingly, he set out to find an explanation for a process which sufficient attention to historical detail renders self-explanatory. He found it in the New Spirit—i.e. a different attitude to life and its values—engendered by the Reformation (*The Protestant Ethic and the Spirit of Capitalism*, trans. by Talcott Parsons, 1930; see also, R. H. Tawney, *Religion and the Rise of Capitalism*, 1926, and, *contra*, H. M. Robertson, *Aspects of the Rise of Economic Individualism; a Criticism of Max Weber and His School*, 1933). The

---

historical objections to this construction are too obvious to detain us. Much more important is it to see the fundamental methodological error involved.

[5] See, e.g., Pierre Duhem's *Les Sources des théories physiques* (1905) and *Les Origines de la statique* (1905-6); also *Études sur Léonard da Vinci* (1906-13).

[6] The subsequent struggle about the Copernican system of astronomy should be briefly noticed, both in order to display the element of truth in the traditional saga and in order to reduce it to its true dimensions. Nicolas Copernicus (1473-1543, completed his manuscript in or about 1530. For decades his idea spread quietly without let or hindrance. It met indeed with opposition and even ridicule from professors who continued to hold on to the Ptolemaic system, but this is only what we should expect in the case of a new departure of such importance. It was this ridicule and not the Inquisition that Galileo feared when, toward the end of the sixteenth century, he became a convinced adherent of Copernicus' theory. The execution (1600) by the Inquisition of another adherent of it, Giordano Bruno, is no proof to the contrary because he also held purely theological views of a heretical nature and, moreover, frankly expressed contempt for the Christian faith. But when Galileo finally decided to come out in support of it (1613 and 1632), the theory was indeed declared heretical by a group of theological advisers of the Inquisition—not, however, by Cardinal Bellarmine—and he was forbidden to hold or teach it; when he failed to keep his promise to submit, he was forced to abjure it and was imprisoned for a fortnight. The point is not only that in this case a purely physical theory was considered theologically obnoxious and that its scientific sponsor was made to suffer for it but also that such an occurrence was an ever present possibility in an age that interpreted scripture more or less literally. This is the element of truth in the saga. But it is clear that the case was quite exceptional; for the bulk of scientific work, that possibility hardly existed at all. Moreover, Galileo's case was complicated by his impulsiveness and his unfortunate talent for personally antagonizing people who were in a position to make their resentment felt. The case of Copernicus himself, and indeed the whole history of the fortunes of his theory up to 1613, suggest that more tactful handling of the matter might have avoided prosecution.

Nor is this at all surprising because, as we have seen, the authority of the Church was not the absolute bar to free research that it has been made out to be. The prevalent impression to the contrary is due to the fact that until recently the world has been content to accept the testimony of the enemies of the Church, which was inspired by unreasoning hatred and unduly dramatized individual events. During the last twenty years or so a more impartial opinion has been gaining ground. This is fortunate for us because it makes it much easier to appreciate scholastic scientific performance in our field.

If, then, we remove a coating of partisan colors, the true picture of the conflict appears without further difficulty. It was primarily political in nature. The laical intellectuals, Catholics no less than Protestants, were often opposed to the Church as a political power, and political opposition against a church very easily turns into heresy. It was this spirit of political opposition and the incidental danger of heresy that the Church sensed—sometimes wrongly, more often rightly—in the works of the laical intellectuals and which made it react even to writings that had nothing to do with either church government or religion and would have passed unnoticed had they been published by a cleric of whose political and religious allegiance the Church was sure. There was, however, another point of limited but, for us, considerable importance. It would seem that the scientific profession does not always absorb novelties with alacrity. Moreover, professors are men who are constitutionally unable to conceive that the other fellow might be right. This holds for all times and places. In Galileo's day, however, the universities were in the hands of monastic orders, except in the countries that had become or were becoming Protestant. These orders welcomed novices and readily opened the scientific career to them. But they did not welcome the scientific work of people who did not want to join them: hence a conflict of interest between two groups of intellectuals that stood in each other's way. And professional resentment against a scientific opponent, of which all ages afford amusing examples, sometimes acquired a connotation that was not amusing under circumstances in which the universities, though they had not always the ear of the Pope, always had the ear of the Inquisition. But this does not mean that those professors themselves did nothing but rehearse Aristotelian texts.

4. Scholastic Sociology and Economics[1]

St. Thomas divided the field of tooled knowledge into the sciences that work by the light of human reason only (*philosophicae disciplinae*), including Natural Theology (*illa theologia quae pars philosophiae ponitur*), and Supernatural Theology (*sacra doctrina*). The latter was also a science but a science

---

[1] During the last half-century, research in medieval economic conditions and processes has grown to proportions that are unmanageable for anyone but the specialist. This literature contains frequent references to economic thought or even analysis, which are, however, made in a spirit and from a standpoint that render them almost useless for our purpose. By far the most serviceable work of this kind that I know, outdated but excellent in its way, is W. J. Ashley's *Introduction to English Economic History and*

sui generis by virtue of the fact that, unlike all other sciences, it makes use not only of human reason but also of revelation. (*Summa* i, quaest. i.) [2] In this schema which seems to have been generally accepted, sociology and economics had no separate compartments of their own. At first, they formed parts of moral theology or ethics, which was itself a part of both supernatural and natural theology. Later on, especially in the sixteenth century, sociological and economic topics were treated within the system of scholastic jurisprudence. Individual questions, mainly about money and interest, were occasionally dealt with separately. So were political questions. But economics as a whole never was. For our purpose, it will be convenient to distinguish three periods in the historical evolution of scholastic thought, according to the degree to which economic problems received attention.

[(a) *From the Ninth Century to the End of the Twelfth.*] The earliest of our periods extends from the ninth century, in the course of which scholastic thought first gathered momentum, to the end of the twelfth. Apart from purely theological questions, it was mainly problems of the theory or philosophy of knowledge which attracted the thinkers of those times. So far as I am able to

---

Theory (1888 and 1893; especially Book i, ch. 3, and Book ii, ch. 6). The standard work on scholastic economic *doctrine*, though marred by serious defects, is still W. Endemann's *Studien in der romanisch-kanonistischen Wirtschafts- und Rechtslehre* (1874 and 1883). Still older and still useful is G. A. L. Cibrario, *Dell'economia politica del Medioevo* (1839). V. Brants' *L'Économie politique au Moyen-Age. Esquisse des théories économiques professées par les écrivains des XIII^e et XIV^e siècles* (1895) and H. Pirenne's *Economic and Social History of Medieval Europe* (English trans. 1936), taken together, complement Ashley's history for the Continent. J. W. Thompson's *Economic and Social History of the Middle Ages* (300-1300) and (1300-1530) [1928 and 1931] does the same. Also see: G. A. T. O'Brien, *An Essay on Mediaeval Economic Teaching* (1920); E. Schreiber, *Die volkswirtschaftlichen Anschauungen der Scholastik* . . . (1913); M. Beer, *Early British Economics from the XIIIth to the Middle of the XVIIIth Century* (1938); H. Garnier, *L'Idée du juste prix* (1900); and B. Jarrett, *Social Theories of the Middle Ages* (1926); some other works will be mentioned later. For 'background' see especially M. de Wulf, *Histoire de la philosophie médiévale* (English trans. by Messenger, 1925-6) and, since the scholastic renaissance in our own day is a phenomenon nobody can afford to neglect, also his *Introduction à la philosophie néo-scolastique* (1904; English trans. by Coffey, 1907). I make no claims for this selection, except that it will suffice to start off further study.

[2] There are two points about this that deserve to be noticed. First, Aristotle defined each science by its subject. But St. Thomas realized that different sciences often deal with the same things (*de eisdem rebus*) and that it is not the subject but the cognitive process (*ratio cognoscibilis*) which identifies a science. Second, St. Thomas did not, of course, deny that Supernatural Theology also used logical procedure (i, quaest. i, art. 8). The real difference is in the source of the starting points (*principia*) which, like other sciences, it takes for granted. These are derived from revelation in the case of Supernatural Theology but in all other sciences, with the possible exception of the purely formal ones, they are derived either from other sciences or else from direct observation of facts. The latter proposition St. Thomas did not state explicitly. But it is clearly implied. If he had stated it explicitly, much misunderstanding of scholastic thought might have been avoided.

make out, no piece of reasoning that could be claimed for the province of economic *analysis* occurs in any of the works of such leaders as, to mention a few, Erigena, Abelard, St. Anselm, or John of Salisbury. Our program, therefore, debars us from considering their performance, though this will fatally limit our conception of the general stream of scholastic thought. But two things must be mentioned nevertheless. We shall call them (I) the Platonic streak and (II) the individualist streak.

I. In the slow and laborious task of intellectual reconstruction that had to be undertaken after centuries during which Europe had been ravaged by barbarian hordes, the remains of ancient learning naturally acquired paramount importance. Most of these remains were, however, not available before the twelfth century and much of the rest was beyond the scholars of the time or was available only in bad translations. Within the little stock, Platonic and Neo-Platonic influences predominated both directly and, through the mediation of St. Augustine's philosophy, indirectly. But Platonic influence will inevitably bring to the fore the problem of Platonic ideas, the problem of the nature of general concepts (*universalia*). Accordingly, the first and most famous of all scholastic discussions in pure philosophy was about this problem; and until the end of the fifteenth century it kept on flaring up again and again. We shall not wonder at this or accept it as proof positive of the sterility of scholastic thought. For it should be clear that this problem represents but a particular form of positing the general problem of pure philosophy. To say that the scholastics never ceased to discuss it therefore means no more than that, while interested in a great many other things, they never ceased to be interested in pure philosophy. On the whole, it may be averred that the 'realistic' view—the view according to which only ideas or concepts, as such, have real existence, and which is therefore the exact opposite of what *we* should call a realistic view—prevailed more or less until the fourteenth century when the battle turned in favor of the opposite, the 'nominalist,' view.[3] But Abelard's (1079-1142) compromise seems to have enjoyed a great, though varying, amount of popularity throughout: the ideas or universals exist independently of any individuals corresponding to them in the mind of God (*universalia* are *ante res*, in this sense); but they are embodied in individual things (*universalia* are therefore also *in rebus*); and the human mind gets a glimpse of them only by observation and abstraction (in which sense they are *post res*).

---

[3] It is important to keep in mind that, in scholastic times, schools of thought tended to be identified, and even to identify themselves, with individual monastic orders. The Franciscan order was, for example, a stronghold of nominalist philosophy. This phenomenon is readily understandable, and I do not think I need explain it. But there is need for emphasizing its importance, for it also shows in other matters: the reason why the late scholastics were so severe on the economics of Duns Scotus—a fact that is not easy to motivate—may perhaps be sought in the antagonism of orders, just as in later ages it is sometimes necessary to invoke the explanatory virtue of antagonisms between national groups of economists—a not unimportant piece of the sociology of science.

This controversy was purely epistemological in nature and has no bearing whatever upon the practice of economic or any other analysis. But it had to be mentioned because, in our own time, the Realism and Nominalism of the scholastic doctors have been linked with two other concepts, Universalism and Individualism, which are held by some writers to be relevant to analytic practice. These writers went so far as to represent Universalism and Individualism as two fundamentally different views of social processes, the conflict between which runs through the whole history of sociological and economic analysis and is indeed the essential fact behind all the other clashes of opinion that occurred throughout the ages.[4] Whatever argument it may be possible to adduce for this doctrine from the standpoint of economic thought or, conceivably, also from the standpoint of a philosophical interpretation of analytic procedures, there is nothing in it that concerns these analytic procedures themselves: the rest of the book will establish this point. Just now we are interested merely in showing that Universalism and Individualism have nothing to do with scholastic Realism and Nominalism. Universalism as opposed to Individualism means that 'social collectives,' such as society, nation, church, and the like, are conceptually prior to their individual members; that the former are the really relevant entities with which the social sciences have to deal; that the latter are but the products of the former; hence that analysis must work from the collectives and not from individual behavior. If, then, we choose to call these collectives sociological universals, then the doctrine in question may indeed be said to oppose universals to individuals. But scholastic Realism opposed universals to individuals in quite a different sense. If I were to adopt scholastic Realism, then my idea of, say, society would claim logical precedence over any individual empirical *society* that I observe but not over individual *men*; the idea of these men would be another universal in the scholastic sense, claiming logical precedence over the empirical individuals. Manifestly, this would imply nothing about either the relation between the two scholastic universals or the relation between any empirical society (a universal in the sense of universalist doctrine) and the empirical individuals comprising it. In particular, I could in this case still be as strong an individualist, politically or in any other sense, as I please. The opposite opinion is thus seen to rest on nothing but an error induced by the double meaning attached to 'universal' and 'individual.' [5]

---

[4] The doctrine of Universalism is usually associated with O. Spann, who is in fact responsible for its success in Germany (for his and his group's publications, see *Encyclopaedia of the Social Sciences*, 'Economics, Romantic and Universalist Economics'). But it is really due to K. Pribram (e.g. Die Entstehung der individualistischen Sozialphilosophie, 1912), who also linked Universalism with scholastic Realism, and Individualism with scholastic Nominalism. I do not hold that the categories Universalist-Individualist are useless for purposes other than ours. Important aspects of economic thought, particularly in its ethico-religious aspects, can perhaps be described by means of them. And the term Universalist is better than the term Socialist, which has acquired a more restricted meaning. Objection is raised only to the improper extension of the field of application of these concepts, which is precisely due to failure to distinguish between economic thought and economic analysis. It is this failure to recognize the epistemological barrier between these two which is to be blamed for the talk about universalist *methods* and even a universal *science* that can only produce confusion.

II. In surveying the history of civilizations, we sometimes speak of objective and subjective cases. By an objective civilization we mean the civilization of a society in which every individual stands in his appointed *niche* and is subject, without reference to his tastes, to superindividual rules; a society that recognizes as universally binding a given ethical and religious code; a society in which art is standardized and all creative activity both expresses and serves superindividual ideals. By a subjective civilization we mean a civilization that displays the opposite characteristics: in which society serves the individual and not the other way round; in short, a society that turns upon, and implements, subjective tastes and allows everyone to build his own system of cultural values. We need not enter into the general question of the analytic standing of such schemes. But we are concerned with the sweeping assertion so often met with that, in the sense explained, medieval civilization was objective and modern civilization is (or until recently was) subjective or individualist, because this touches, or may be supposed to touch, upon the 'spirit' in which people conducted or conduct their economic analysis. There cannot be any doubt that some of the characteristics fit—religious life in the age of 'One God, One Church,' as compared to religious life in the age of hundreds of denominations, is the standard example. But neither can there be any doubt that as a whole those abstract pictures are ludicrously inadequate. Is it possible to imagine a fiercer individualist than a knight? Did not the whole trouble that medieval civilization experienced with military and political management (and which largely accounts for its failures) arise precisely from this fact? And is the member of a modern labor union or the mechanized farmer of today really so much more of an individualist than was the medieval member of a craft guild or the medieval peasant? Therefore, the reader should not be shocked to learn that the individualist streak in medieval thought also was much stronger than is commonly supposed. This is true, both in the sense that opinion was much more differentiated individually and in the sense that the individual phenomenon and (in speculations about society) the individual man were much more carefully attended to than we are apt to think. Scholastic sociology and economics, in particular, are strictly individualist, if we understand this to mean that the doctors, so far as they aimed at description and explanation of economic facts, started invariably from the individual's tastes and behavior. That they applied superindividual canons of justice to these facts is not relevant to the logical nature of their analysis; but even these canons were derived from a moral schema in which the individual was an end in himself and the central idea of which was the salvation of individual souls.

---

[5] By the same token, we must not label Abelard as individualist on the ground that he seems to have coined the phrase: *nihil est praeter individuum.*

[(b) *The Thirteenth Century.*] Our second period, speaking roughly, covers the thirteenth century. There is justification for calling it the classic period of scholasticism so far as theology and philosophy are concerned. Theological and philosophical thought was indeed not only revolutionized but also consolidated into a new system that was all that the term Classic implies. Chiefly, this revolution was the work of Grosseteste, Alexander of Hales, St. Bonaventura, and Duns Scotus (Franciscan school) on the one hand, and of Albertus Magnus and his disciple, St. Thomas (Dominican school), on the other. The consolidation, that is, the creation of the classic system, was the towering achievement of St. Thomas alone. But in other respects, there was only revolution and no consolidation. That century, indeed, gave birth to scholastic science as distinguished from theology and philosophy; it produced work that initiated and laid the foundations for further work, but it did not establish anything beyond starting points. This holds for the social as well as for the physical sciences. It should be particularly noticed that, as the example of Grosseteste shows, interest in mathematical and physical research was widespread even among men who did no such research themselves. Roger Bacon was a peak, but not a solitary peak; and plenty of men, without and within the Franciscan order, stood ready to go on in his line of advance. The reason why this does not stand out as it should is that the scholastic physicists and mathematicians of the subsequent four centuries tended to become specialists in their particular fields and their scholastic background is easily lost from sight. For instance, we look upon Francesco Cavalieri (1598-1647) simply as a great mathematician. It does not occur to us to associate the origins of the integral calculus with scholasticism in general or with the Jesuit order in particular, though as a matter of fact Cavalieri was the product of both.[6]

In itself, that theologico-philosophical revolution is no concern of ours. But one aspect of it is of considerable importance for the history of sociological and economic analysis, namely, the resurrection of Aristotelian thought. During the twelfth century more complete knowledge of Aristotle's writings filtered slowly into the intellectual world of western Christianity, partly through Semite mediation, Arab and Jewish.[7] To the scholastic doctors this meant two things. First, Arab mediation meant Arab interpretation, which was unacceptable to them in some matters of epistemology as well as of theology. Second, access to Aristotle's thought immensely facilitated the gigantic task before them not only in metaphysics, where they had to break new paths, but also in the physical and social sciences, where they had to start from little or nothing.

---

[6] Roger Bacon (1214?-92), the *doctor mirabilis* of scholastic tradition, affords another case that illustrates the nature and the causes of the troubles that were experienced by some eminent physicists. He was still more aggressive than was Galileo 400 years later. In all ages people react unfavorably to being called fools. In rough ages they react roughly.

[7] Avicenna (Ibn Sina, 980-1037), the Arab physician-philosopher, and Averroës (Ibn Rushd, 1126-98), the lawyer-philosopher of Cordoba, and Moses Maimonides (1135-1204) the Hebrew theologian-philosopher (especially his *Guide of the Perplexed*, Eng-

The reader will observe that I do not assign to the recovery of Aristotle's writings the role of chief *cause* of thirteenth-century developments. Such developments are never induced solely by an influence from outside. Aristotle came in, as a powerful ally, to help and to provide implements. But perception of the task and the will to rush forward were, of course, there independently of him. An analogy will clear up this point. We have had occasion to refer to the partial adoption or 'reception' of the *Corpus juris civilis* in the later Middle Ages and the Renaissance. This phenomenon cannot be causally explained by a lucky discovery of a few old volumes coupled with the naïve belief of uncritical minds that these volumes contained legal material that was still in force. The economic process was evolving patterns of life that called for legal forms, especially for a system of contracts, of the type that the Roman jurists had worked out. There can be no doubt but that the lawyers of the Middle Ages would have eventually worked out similar forms for themselves. The Roman law came in usefully, not because it brought something that was foreign to the spirit and needs of the age—so far as it did this, its reception was in fact an unmitigated nuisance—but precisely because it presented, ready made, what without it would have had to be produced laboriously. Similarly, the 'reception' of Aristotle's teaching was principally a most important time- and labor-saving device, particularly in those fields that were as yet waste lands. It is in this light—and not in the light of the theory that there was passive acceptance of a lucky discovery—that we must see the relation between Aristotelism and scholasticism.

But so soon as the scholastic doctors realized that in Aristotle's writings they had all, or nearly all, they could hope for at the moment and that with the help of his doctrines they might accomplish what it would have cost them a century's work to do by themselves, they naturally made the most of this opportunity. Aristotle became for them *the* philosopher, the universal teacher, and most of their work took the form of expounding him to students and to the public at large, and of commenting upon him. Moreover, his writings served admirably for didactic purposes since they were in fact summarizing and systematizing textbooks. In consequence, it was in the role of expounders of, and commentators on, Aristotelian doctrine that Grosseteste, Albertus Magnus,

---

lish trans. by Friedländer, 1881-5) should be mentioned in this connection. The problem of reconciling Aristotle's teaching with Hebrew theology presented itself to Maimonides in much the same manner as the analogous problem presented itself to the Christian doctors.

and the other leaders mentioned above appeared to the public of their own and of later times. St. Thomas himself became, for many people, simply the man who had succeeded in harnessing Aristotle for the service of the Church. This misconception of the revolution of the thirteenth century and, in particular, of St. Thomas' performance was not corrected but, on the contrary, was fostered by the scientific practice of the next 300 years. For Aristotle's work continued to provide the systematic frame for the growing scientific material and to supply the need for nicely pedestrian texts; everything, therefore, continued to be cast in the Aristotelian mold—nothing so completely as scholastic economics, which also illustrates the way in which, by this convenient practice, the scholastic doctors were likely to lose the credit for their original contributions.

This explains not only the otherwise quite incomprehensible success of Aristotelian teaching through these 300 years but also the penalty the ancient sage was eventually to pay for this success. We may just as well complete the story which is so full of interest to the student of the tortuous ways of the human mind. We have seen that there was nothing in the scholastic system to bar new developments within it or even developments away from the ground taken by its classic works. Descartes' philosophy may exemplify such a development.[8] He displayed no hostility to the old scholastic philosophy and, among other things, accepted St. Anselm's proof of the existence of God—rejected by St. Thomas—as the basis of his own theory of the *cogito*. There is plenty of room for doubt as to how much this amounts to. But it certainly suffices for speaking of peaceful evolution from scholastic backgrounds. We have also seen, however, that scholasticism became a bugbear, as the influence of laical intellectuals asserted itself. And wherever hostility to scholasticism asserted itself, hostility to Aristotle asserted itself also: because Aristotelism was the vessel of scholastic thought, hostility to Aristotelism became the vessel of hostility to the doctors. There were even anti-scholastic and anti-Aristotelian scholastics of whom Gassendi is the outstanding example.[9] His mathematical and physical work, entirely neutral in itself, acquired a critical connotation by the way in which he advocated the cause of experimental—'empiricist' or 'inductive'—methods rather than by this advocacy as such. In philosophy he replaced the Aristotelian basis (substantially) by one essentially Epicurean. However, it was of course among the laical enemies of the Catholic doctors that it became the fashion to represent Aristotle as the incarnation of old dust and of futility. Paracelsus had Aristotelian books solemnly burned before starting his medical lectures; Galileo, in the famous dialogue on the heliocentric system that gave so much offense, made a comic figure of the inept Aristotelian objector; Francis Bacon, in espousing the cause of 'inductive' science, contrasted it with both scholastic and Aristotelian speculation. All this was unfair to the scholastic doctors. But it was still more unfair to the old sage. For if there is any general message at all that speaks to us from his pages, it is surely the message of empirical research.[10] So true is it that, in science as elsewhere, we fight for and against not men and things as they are, but for and against the caricatures we make of them.[11] However, let us return to the classic period, the thirteenth century, in order to search for elements of sociological and economic analysis.

---

[8] René Descartes (1596-1650). For the purpose in hand, only his *Essais philosophiques* (1637) is relevant. He was the mediator between medieval and modern philosophy, and was the product of Jesuit education.

[9] Pierre Gassendi (1592-1655) was a philosopher, mathematician, and physicist, a professor in holy orders whom, on his actual work, nobody would think of excluding from the scholastic circle. But he went out of his way to distance himself from it. Of his works those most important for us are: *Exercitationes paradoxicae adversus Aristoteleos* (1624); *Syntagma philosophiae Epicuri*, 1649 (works ed. by Montmort, 1658); see also G. S. Brett, *The Philosophy of Gassendi* (1908).

We find small beginnings only—little of sociology, still less of economics. In part this was doubtless due to lack of interest. St. Thomas, in particular, was indeed interested in political sociology but all the economic questions put together mattered less to him than did the smallest point of theological or philosophical doctrine, and it is only where economic phenomena raise questions of moral theology that he touches upon them at all. Even where he does we do not feel, as we do elsewhere, that his powerful intellect is all there, passionately resolved to penetrate into the core of things but rather that he is writing in obedience to the requirements of systematic completeness. More or less, this applies to all his contemporaries. In consequence, Aristotle's teaching sufficed for them and they hardly ever went beyond it. There was indeed a difference in moral tone and cultural vision and also a shift of emphasis that is accounted for by the different social patterns they beheld. But neither is so important as we might have expected. Since these things are of no great moment in a history of economic analysis, it will suffice to note that the scholastic doctors looked upon physical labor as a discipline favorable to Christian virtue and as a means of keeping men from sinning, which implies an attitude entirely unlike that of Aristotle; that with them slavery was no longer a normal, let alone fundamental, institution; that they gave their blessings to charity and to voluntary poverty; that their ideal of a *vita contemplativa* carried, of course, a meaning that was quite foreign to Aristotle's corresponding ideal of life, though there are important similarities between the two; that they repeated but qualified Aristotle's views on commerce and commercial gain.

---

[10] Theophrastus Bombastus von Hohenheim, who called himself Paracelsus (1490?-1541), was a physician and chemist of eminence though not without an element of charlatanism. Francis Bacon (1561-1626; works ed. by Spedding, Ellis, and Heath, 1857-62) presumably needs no introduction. The tremendous success of his writings—not so much in his day but during the Enlightenment and then during the nineteenth century—is amply accounted for by the fact that he expressed with supreme ability what a rapidly increasing number of people actually came to believe. He was the very type of a 'representative man.' But precisely because he was and because in consequence his figure stands out so clearly, his ideas now seem much more novel and much less in keeping with previous developments than they were. Therefore, his writings inculcated into the public mind the unreal contraposition of inductive research and scholasticism in which, along with his contemporaries, he himself was so fond of believing, the more so because he probably knew very little about the work of the scholastics. More than any other individual, he helped to foster the delusion that to this day distorts the history of thought.

[11] Outstanding examples from the history of economics are A. Smith's criticism of the 'mercantilists' and Schmoller's criticism of the English 'classics.' Both cases will be discussed in their places.

While all the other points apply to scholastic doctrine of all ages, the one mentioned last holds fully only for the classic period. After the thirteenth century a significant change occurred in the attitude of the scholastic doctors to commercial activity. But the thirteenth century scholastics undoubtedly held the opinion expressed by St. Thomas, namely, that there is 'something base' about commerce in itself (*negotiatio secundum se considerata quandam turpitudinem habet, Summa* II, 2, quaest. LXXVII, art. 4), though commercial gain might be justified (a) by the necessity of making one's living; or (b) by a wish to acquire means for charitable purposes; or (c) by a wish to serve *publicam utilitatem*, provided that the lucre be moderate and can be considered as a reward of work (*stipendium laboris*); or (d) by an improvement of the thing traded; or (e) by intertemporal or interlocal differences in its value; or (f) by risk (*propter periculum*). St. Thomas' wording leaves some room for doubt about the conditions in which he was prepared to admit considerations (d) (f), and it may be true that others, especially Duns Scotus (1266-1308) and a doctor whom I have not mentioned so far, Richard of Middleton (1249 1306), went somewhat further, especially as regards justifying the social usefulness of the practice of buying in a cheaper market and selling in a dearer one. However, even qualifications (b) and (c) go beyond Aristotle's teaching. The emphasis all these authors place upon the element of remuneration of some socially useful activity has given rise, on the one hand, to the opinion, which may be correct, that the source of the (moral) 'right to the produce of one's labor' may be found in the scholastic literature, and, on the other hand, to the error that the scholastic doctors held a (analytic) labor theory of value, that is, that they *explained* the phenomenon of value by the fact that (most) commodities cost labor. For the moment, the reader should only notice that there is no logical relation between mere emphasis upon the necessity, moral or economic, of remunerating *labor* (no matter whether we translate the Latin word by the English 'labor' or by 'activity' or 'effort' or 'trouble') and what is technically known as the labor theory of value.

St. Thomas' sociology of institutions,[12] political and other, is not what readers will expect who are in the habit of tracing the political and social doctrines of the nineteenth century to Locke or to the writers of the French Enlightenment or to the English utilitarians. Considering that, in this respect, the teaching of St. Thomas not only was representative of that of his contemporaries but also was accepted by all the scholastic doctors of later times, its main points should be briefly indicated. There was the sacred precinct of the Catholic Church. But for the rest, society was treated as a thoroughly human affair, and moreover, as a mere agglomeration of individuals brought together by their mundane needs. Government, too, was thought of as arising from and existing for nothing but those utilitarian purposes that the individuals cannot realize without such an organization. Its *raison d'être* was the Public Good. The ruler's power was derived from the people, as we may say, by delegation. The people are the sovereign and an unworthy ruler may be deposed. Duns Scotus came still nearer to adopting a social-contract theory of the state.[13] This mixture of sociological analysis and normative argument is remarkably individualist, utilitarian, and (in a sense) rationalist, a fact that it is important to remember in view of the attempt we are going to make to link this body of ideas with the laical and anti-Catholic political philosophies of the eighteenth century. There is nothing metaphysical about this part of scholastic doctrine. Nor did the Catholic doctors countenance political authoritarianism. The divine right of monarchs, in particular, and the concept of the omnipotent state are creations of the Protestant sponsors of the absolutist tendencies that were to assert themselves in the national states.

---

[12] Our main source for St. Thomas' political sociology is a tract entitled *De regimine principum*, widely used throughout the Middle Ages, and a letter to a Duchess of Brabant. But only part of the former is certainly by St. Thomas himself; the rest may be the work of another Dominican, Ptolemy of Lucca (d. 1327).

The individualist and utilitarian streak and the emphasis upon a rationally perceived Public Good run through the whole sociology of St. Thomas. One example will suffice: the most important one, the theory of property. Having disposed of the theological aspects of the matter, St. Thomas simply argues that property is not against natural law but an invention of the human reason,[14] which is justifiable because people will take better care of what they possess for themselves than of what belongs to many or all; because they will exert themselves more strenuously on their own account than on account of others; because the social order will be better preserved if possessions are distinct, so that there is no occasion for quarreling about the use of things possessed in common—considerations that attempt to define the social 'function' of private property much as Aristotle had defined them before and much as the nineteenth-century textbook was to define them afterward. And since he found in Aristotle all he wished to say, he referred to him and accepted his formulations.

---

[13] This theory was not, of course, applied to the government of the Catholic Church. When this was done by Marsilius of Padua (c. 1270–1342; *Defensor pacis*, 1326), it spelled heresy. From our standpoint two observations suggest themselves: first, the case illustrates how implicit acceptance of supermundane authority in some respects may in practice be complemented by extreme freedom of thought and action in other respects; second, the case also shows why the question of the influence of supermundane authority upon analysis cannot be answered once for all, but must be answered separately for every individual argument. Since too much care cannot be expended on clearing up this point, let us, by way of supplementing previous argument, introduce the following tripartite distinction which applies to all authorities that ever did or do attempt to direct opinion. First, as the case in hand shows, there were matters in which the Catholic Church prescribed opinion and barred analysis that led to any other results. Second, there were many matters in which, being indifferent to both opinion and analysis, it did not interfere in any way. Third, there were matters (such as interest) in which it prescribed opinion in the sense of moral judgment but did not bar analysis of facts.

[14] *Summa* II, 2, quaest. LXVI, art. 2: *proprietas possessionum non est contra jus naturale, sed juri naturali superadditur per adinventionem rationis humanae*. On the meaning to be attached to *jus naturale*, see next section.

This holds with added force for St. Thomas' 'pure economics' (*oeconomia* with him means, however, simply household management). It was embryonic and really consists of only part of his argument on Just Price (*Summa* II, 2, quaest. LXXVII, art. 1) and on Interest (*Summa* II, 2, quaest. LXXVIII). The relevant part of the argument on just price—the price that assures the 'equivalence' of commutative justice—is strictly Aristotelian and should be interpreted exactly as we have interpreted Aristotle's. St. Thomas was as far as was Aristotle from postulating the existence of a metaphysical or immutable 'objective value.' His *quantitas valoris* is not something different from price but is simply normal competitive price. The distinction he seems to make between price and value is not a distinction between price and some value that is not a price, but a distinction between the price paid *in an individual transaction* and the price that 'consists' in the public's evaluation of the commodity (*justum pretium . . . in quadam aestimatione consistit*), which can only mean normal competitive price, or value in the sense of normal competitive price, where such a price exists.[15] In cases where no such price exists, St. Thomas recognized, as coming within his concept of just price, the element of the subjective value of an object to the seller, though not the element of the subjective value of the object for the buyer—a point that is important for scholastic treatment of interest. Beyond this he did not go in the article referred to. But other passages, perhaps, support the opinion that, by implication at least, he did take a step beyond Aristotle which was more explicitly taken by Duns Scotus, Richard of Middleton, and possibly others. Duns Scotus, at all events, may be credited with having related just price to cost, that is, the producers' or traders' expenditure of money and effort (*expensae et labores*). Though he presumably thought of nothing beyond providing a more precise criterion of scholastic 'commutative justice'—which was rightly rejected by the later scholastics—we must nevertheless credit him with having discovered the condition of competitive equilibrium which came to be known in the nineteenth century as the Law of Cost. This is not imputing too much: for if we identify the just price of a good with its competitive common value, as Duns Scotus certainly did, and if we further equate that just price to the cost of the good (taking account of risk, as he did not fail to observe), then we have ipso facto, at least by implication, stated the law of cost not only as a normative but also as an analytic proposition.

Following Alexander of Hales and Albertus Magnus, St. Thomas condemned interest as contrary to commutative justice on a ground that proved a conundrum for almost all his scholastic successors: interest is a price paid for the use of money; but, viewed from the standpoint of the individual holder, money is consumed in the act of being used; therefore, like wine, it has no use that could be separated from its substance as has, for example, a house; therefore charging for its use is charging for something that does not exist, which is illegitimate (usurious). Whatever may be thought of this argument, which among other things neglects the possibility that 'pure' interest might be an element of the price of money itself—instead of being a charge for a separable use[16]—one thing is clear: exactly like the somewhat different Aristotelian argument, it does not bear at all upon the question why interest is actually paid. Since this question, the only one that is relevant to economic analysis, was actually raised by the later scholastics, we defer the consideration of the clues for an answer, which St. Thomas' reasoning nevertheless suggests.

---

[15] This interpretation is supported by the fact that the *quaestio*, in which the theory of just price is presented (quaest. LXXVII of II, 2) is entitled *De fraudulentia* and, in fact, mainly deals with frauds perpetrated by sellers. If the just price were something else than the normal competitive price, practices other than fraud would be more important. But if St. Thomas was thinking of what we call normal competitive price, fraud becomes the chief phenomenon to be dealt with. For if there exists a competitive market price, individual deviations from it are hardly possible except through fraudulent representations about the quantity and quality of the goods.

[(c) *From the Fourteenth Century to the Seventeenth.*] The last of the three periods into which we have decided to divide the history of scholasticism extends from the beginning of the fourteenth century to the first decades of the seventeenth. It comprises practically the whole of the history of scholastic economics. But, having already fully explained the setting and the nature of scholastic work, we can now afford to be brief. In particular, no further explanation seems to be needed for the ease with which the economics of the doctors absorbed all the phenomena of nascent capitalism and, in consequence, for the fact that it served so well as a basis of the analytic work of their successors, not excluding A. Smith.

In order to achieve the maximum of economy, I shall mention only a very few representative names and then attempt to draw a systematic sketch of what I conceive the state of scholastic economics to have been about 1600. Other names, of course, would have to be mentioned for other purposes; we are artificially narrowing down what was a very broad and deep stream.

For the fourteenth century we choose Buridanus and Oresmius as representatives.[17] The latter's treatise on money is usually described as the first treatise entirely devoted to an economic problem. But it is mainly legal and political in nature and really does not contain much strictly economic material—in particular, nothing that was not current doctrine among the scholastics of the time—its chief purpose being to combat the prevalent practice of debasing money, a topic that was treated later on in a copious literature to be briefly noticed presently. Our fifteenth-century representatives will be St. Antonine of Florence, perhaps the first man to whom it is possible to ascribe a comprehensive vision of the economic process in all its major aspects, and Biel.[18] For the sixteenth century we select Mercado and, as representatives of the literature on Justice and Law (*De justitia et jure*) that in the sixteenth century became the main scholastic repository of economic material, the three great Jesuits whose works have been recently analyzed by Professor Dempsey—Lessius, Molina, and de Lugo.[19]

---

[16] The reason why St. Thomas did not consider this possibility was obviously that he placed implicit confidence in the proposition that the price of any commodity that is chosen for the standard of value is unity by definition. Reasoning on from this, we may easily arrive at the conclusion that any 'pure' premium cannot be anything else but a fraudulent charge for a nonexistent use, since the price of the substance or 'capital' must necessarily be equal to the capital itself.

[17] Joannes Buridanus (Jean Buridan, fl. 1328-58), professor in the University of Paris. Of his many works, all drawn up on the Aristotelian frame, the most important for us are: *Quaestiones in decem libros Ethicorum Aristotelis* (ed. used, 1637) and *Quaestiones super octo libros Politicorum Aristotelis* (ed. used with notes by G. Baterel, 1513). His theory of volition (*Summula de dialectica*, 1487, and *Compendium logicae*, 1487) led up to the familiar paradox of the logic of choice that is illustrated by the perfectly rational ass that starves between two equally attractive bundles of hay owing to his inability to make up his mind which to consume first. Nicole Oresme (1320?-82), Bishop of Lisieux, was a man of polyhistoric interests who also wrote on theology, mathematics, and astronomy. The work in question, *Tractatus de origine et jure nec non*

---

et de mutationibus monetarum, was written between 1350 and 1360 (ed. used 1605). An extract is included in Monroe's *Early Economic Thought*, pp. 79-102. After having met with great success in its own time, it seems to have falllen into oblivion from which it was rescued by F. Meunier, *Essai sur la vie et les ouvrages de Nicole Oresme* (1857) and especially by W. Roscher ('Ein grosser Nationalökonom des vierzehnten Jahrhunderts' in *Zeitschrift für die gesamte Staatswissenschaft*, 1863), who extolled its merits, particularly its originality, beyond all reason, as discoverers of forgotten worthies are apt to do—which naturally induced a reaction. There is quite a literature on Oresme. Let us single out C. A. Conigliani, *Le dottrine monetarie in Francia durante il medio evo* (1890).

[18] St. Antonine (Antonio Pierozzi, also called Forciglioni; 1389-1459), Archbishop of Florence, *Summa theologica* (ed. used: for the first and second parts, Lyons, 1516; for the third, Venice, 1477); also *Summa moralis* (Verona, 1740). See B. Jarrett, *S. Antonino and Mediaeval Economics* (1914). Gabriel Biel (1425?-95), professor in the University of Tübingen, another discovery of Roscher's (*Geschichte der Nationalökonomik in Deutschland*, 1874). His *Tractatus de potestate et utilitate monetarum* (1541; English trans., 1930) does not, however, contain anything that cannot be found in earlier writers. Why he should have been called the last of the scholastics I am unable to understand. But I have chosen him for reference because perusal of his work is particularly effective in destroying prejudices concerning the spirit of scholasticism. Really more important seems to be Panormitanus (Nicolaus dei Tedeschi or Tudeschi, Archbishop of Palermo, 1386-1445) to judge from quotations in the later scholastic literature.

[19] The choice was a difficult one and may give rise to valid objection particularly against the exclusion of such men as John Major (d. 1549; cf. the comments of Ashley in *Economic History* I, Part II), Navarrus (Martinus de Azpilcueta, d. 1586), Domingo de Soto (*De justicia et jure*, 1553), and Gaetanus (Cardinal Cajetan, Tommaso de Vio, 1468-1534) all of whom we shall have to mention, and others. Tomás de Mercado, author of *De los tratos de India y tratantes en ellas* (1569; enlarged ed. of 1571, the only one known to me, under the title *Summa de tratos y contratos*), has been included only because of his 'quantity theory of money' and cannot be put on the same level with Lessius, Molina, and de Lugo in any other respect. But I am positive that the latter three must be included in any history of economics, though there was a further motive for selecting them: Professor Dempsey's book (B. W. Dempsey, *Interest and Usury*, 1943, chs. VI-VIII) contains a full exposition of their economics; this book com-

All that need be said about the sociology of the later scholastics is that they developed, in greater detail and with a fuller perception of implications, the ideas that had crystallized in the works of their thirteenth-century predecessors. Their political sociology in particular retained the same method of approach to the phenomena of state and government and also the same 'radical' spirit.[20] Their economic sociology, especially their theory of property, continued to treat temporal institutions as utilitarian devices that were to be explained—or 'justified'—by considerations of social expedience centering in the concept of the Public Good. And this social expedience might, according to historical circumstances, sometimes tell in favor, and sometimes tell against, private property. They no doubt believed that in civilized societies, that is, in societies that were past the early or natural state in which all possessions were common to all (*omnia omnibus sunt communia*), these considerations told in favor of private property (*divisio rerum*); but there was neither a theoretical nor a moral principle to prevent them from arriving at the opposite result whenever new facts should suggest it.[21] Some methodological aspects of this will be dealt with in the next section. But another point should be briefly mentioned.

The scholastics were not primarily concerned with the problems of the national states and their power politics. This is precisely one of the most important links between them and the 'liberals' of the eighteenth and even the nineteenth centuries. But some of the phenomena that accompanied the rise of these states were, nevertheless, bound to attract their critical attention, and among them was fiscal policy. I mention this here, and not in connection with their economics, because they hardly went at all into the specifically economic problems of public finance, such as incidence of taxation, economic effects of government expenditure, and the like: even when they did discuss government borrowing (which, following the lead of St. Thomas, they mostly condemned) or the question of the relative merits of taxes on wealth and taxes on consumption (Molina, Lessius, and de Lugo, among others, touched upon

---

bines to a degree that is quite exceptional, thorough familiarity with scholastic thought and with economic theory, so that the interested reader may be referred to it with confidence. Lessius (Leonard de Leys, 1554-1623), Luis Molina (1535-1600), and de Lugo (Juan de Lugo, 1583-1660) all wrote treatises *de justitia et jure*. Our chief guide will be Molina. His treatise appeared in instalments in 1593, 1597, and in and after 1600; (ed. used *De justitia et jure*, 1659).

[20] Any doubt about this may be dispersed by a single reference: Juan de Mariana, *De rege et regis institutione*, 1599. But even scholastics who did not go so far never worshiped at the shrines of either absolute monarchs or omnipotent bureaucracies, see e.g., Molina, *Tractatus secundus, disp.* 22 and 26. The scholastic doctors, following their own earlier tradition, must therefore be considered as the most important of the 'monarchomachs' of the sixteenth century. On these, see especially J. W. Allen, *A History of Political Thought in the Sixteenth Century*, 1928.

[21] The reader will find a very characteristic quotation from Lessius in Dempsey's *Interest and Usury*, p. 132. It does not follow, of course, that Lessius, were he alive today, would embrace political communism. The point is that in good logic he would be *free* to arrive at the conclusion that private property no longer fulfils the requirements of social expedience and that economic communism does.

this question), they produced nothing that qualifies as economic analysis. What they were most interested in was the 'justice' of taxation in the widest acceptance of the term—such questions as whether and when taxes might be rightfully imposed, by whom and on whom, for what purposes, and to what extent. And below their normative propositions there was some sociological analysis of the nature of taxation and of the relation between state and citizen. Both these norms and this analysis, along with the rest of their political and economic sociology, went into the work of their laical successors though the later science of public finance grew mainly from other roots.[22]

But while the economic sociology of the scholastic doctors of this period was, in substance, not more than thirteenth-century doctrine worked out more fully, the 'pure' economics which they also handed down to those laical successors was, practically in its entirety, their own creation. It is within their systems of moral theology and law that economics gained definite if not separate existence, and it is they who come nearer than does any other group to having been the 'founders' of scientific economics. And not only that: it will appear, even, that the bases they laid for a serviceable and well-integrated body of analytic tools and propositions were sounder than was much subsequent work, in the sense that a considerable part of the economics of the later nineteenth century might have been developed from those bases more quickly and with less trouble than it actually cost to develop it, and that some of that subsequent work was therefore in the nature of a time- and labor-consuming detour.

In what may be described as the applied economics of the scholastic doctors, the pivotal concept was the same Public Good that also dominated their economic sociology. This Public Good was conceived, in a distinctly utilitarian spirit, with reference to the satisfaction of the economic wants of individuals as discerned by the observer's reason or *ratio recta* (see, below, next section)—and is therefore, barring technique, exactly the same thing as the welfare concept of modern Welfare Economics, Professor Pigou's for instance. The most important link between the latter and scholastic welfare economics is the welfare economics of the Italian economists of the eighteenth century (see below, ch. 3). So far as appraisal of economic policy and business practice is concerned, the scholastics' idea of what is 'unjust' was associated—though never identified—with their idea of what is contrary to public welfare in that sense. To give at least one example: Molina declared that monopoly was in general (*regulariter*) unjust *and* harmful to the public welfare (*tract.* II, *disp.* 345); though he did not identify the two, their juxtaposition is nevertheless significant.

The welfare economics of the scholastic doctors linked up with their 'pure' economics through the pivotal concept of the latter, Value, which also was based upon 'wants and their satisfaction.' Of course, there was nothing new in this starting point itself. But the Aristotelian distinction between value in use and value in exchange was deepened and developed into a fragmentary but genuine subjective or utility theory of exchange value or price in a manner for which there was no analogue in either Aristotle or St. Thomas, though there was in both what we may describe as a pointer. First, by way of criticizing Duns Scotus and his followers, the late scholastics, particularly Molina, made it quite clear that cost, though a factor in the determination of exchange value (or price), was not its logical source or 'cause.'[23] Second, they adumbrated with unmistakable clearness the theory of the utility which they considered as the source or cause of value. Molina and Lugo, for instance, were as careful as C. Menger was to be to point out that this utility was not a property of the goods themselves or identical with any of their inherent qualities, but was the reflex of the uses the individuals under observation proposed to make of these goods and of the importance they attached to these uses. But a century before that, St. Antonine, evidently motivated by the wish to divest the relevant concept of undesirable 'objective' meanings, had employed the unclassical but excellent term *complacibilitas*—the exact equivalent of Professor Irving Fisher's 'desiredness,' which also is used to express the fact that a thing is actually being desired and nothing else. Third, the late scholastics, though they did not explicitly resolve the 'paradox of value'—that water though useful has normally no exchange value—obviated the difficulty by making their utility concept, from the first, relative to abundance or scarcity; their utility was not utility of goods in the abstract, but utility of the *quantities* of goods available or producible in the individual's particular situations. Finally, fourth, they listed all the price-determining factors,[24] though they failed to integrate them into a full-fledged theory of demand and supply. But the elements for such a theory were all there and the technical apparatus of schedules and of marginal concepts that developed during the nineteenth century is really all that had to be added to them.

---

[22] The fact should, however, be recorded, that Nicolaus Cusanus (already mentioned in connection with the heliocentric theory) framed a comprehensive plan for the reform of the finances of the German Empire, based upon a general income tax (actually introduced, for the Empire as distinguished from the component states, in 1920).

There are two more aspects of this theory of exchange value that deserve to be noticed. On the one hand, the late scholastics identified their just price not, as Aristotle and also Duns Scotus seem to have done, with *normal* competitive price but with any competitive price (*communis estimatio fori* or *pretium currens*). Wherever such a price existed, it was 'just' to pay and to accept it, whatever the consequences might be for the trading parties: if merchants, paying and accepting market prices, made gains, this was all right, and if they suffered losses, this was bad luck or else a penalty for incompetence *so long as gain or loss resulted from the unhampered working of the market mechanism though not if it resulted, for example, from price fixing by public authority or monopolistic concerns.*[25] Molina's disapproval of price fixing, though qualified, and his approval of gains arising from high competitive prices in times of scarcity are no doubt ethical judgments. But they reveal a perception of the organic functions of commercial gains and of the price fluctuations that are responsible for them, a fact that marks a considerable step in analysis. This should be borne in mind, for we are not as a rule in the habit of looking to the scholastics for the origin of the theories that are associated with nineteenth-century laissez-faire liberalism.

---

[23] This statement, I think, renders fairly the meaning of Molina's argument in *tract.* II, *disp.* 348, if proper attention is paid to the analytic kernel in the word 'just.' Still less than a cost theory of value can a labor theory of value be imputed to them, though this has been done. We shall see later that the emotional appeal of the latter has induced some historians to interpret as many authors as possible in this sense. It should be borne in mind, therefore, that mere emphasis on the importance in the economic process of the element of labor or effort or trouble does not amount to sponsorship of the proposition that expenditure of labor *explains*, or is *causal* to, value—which is what is meant by labor theory of value in this book.

[24] Cf. especially a passage in Lessius, quoted by Dempsey, op. cit. p. 151.

On the other hand, the late scholastics analyzed economic activity itself—St. Antonine's *industria*—and particularly commercial and speculative activity, from a standpoint that was diametrically opposed to Aristotle's. The Economic Man of later times put in an appearance in the conception of 'prudent economic reason'—a Thomistic phrase which acquired an entirely un-Thomistic connotation by de Lugo's interpretation, which was to the effect that this prudence implies the intention of gaining in every legitimate way. This did not spell moral approval of profit hunting. As far as that goes, it is safe to assume that neither de Lugo's nor any other scholastic doctor's feelings differed from Aristotle's; St. Antonine, for example, was very explicit on this point. But it spelled an improved analysis of business facts that was, of course, partly induced by observation of the phenomena of rising capitalism This realistic character of the work of the late scholastics should be particularly emphasized. They did not simply speculate. They did all the fact-finding that it was possible for them to do in an age without statistical services. Their generalizations invariably grew out of discussions of factual patterns and were copiously illustrated by practical examples. Lessius described the practice of the Antwerp exchange (*bursa*). Molina sallied forth from his study to interview businessmen about their methods. Some of his investigations into the economic conditions of his time and country, such as his study of the Spanish wool trade, amount to little monographs.

As regards money, it will suffice to record the four following points. First, reasoning on Aristotelian lines, the doctors presented, practically to a man, a strictly metallist theory of money which, in fundamentals, did not differ from that of A. Smith; we find the same genetic or pseudo-historical deduction from the necessity of avoiding the inconveniences of direct barter, the same conception of money as the most saleable commodity, and so on. Second, they were not only theoretical but also practical metallists, disapproving, with varying degrees of severity, of debasement and of any gain that accrued from it to princes. As mentioned before, the outstanding authority on this matter, Oresmius, only formulated the doctors' common opinion, which in this case was evidently shared by most people.[26] The modern student of monetary theory, who may possibly sympathize with those princes and feel inclined to regard them as worthy predecessors of the governments of his own day, should observe that the doctors went but a very short way into the economic effects of devaluation. They saw the effect on prices and felt that creditors and holders of money were being defrauded but that was about all. Even in these matters their analysis did not go beyond the obvious, and the idea that devaluation—and other methods of increasing the amount of circulating monetary units—might stimulate trade and employment was quite foreign to them; it first occurred to those businessmen who wrote on monetary policy in the seventeenth century (see below, ch. 6). Since this idea was almost entirely lost on the

[26] Oresme, op. cit. ch. xv: *Quod lucrum quod provenit Principi ex mutatione monetae sit injustum.* Cf. Jean Bodin's precept in the sixth Book of his *De re publica* (Les six livres de la République): *princeps a nummorum corruptela debet abstinere.* This adage and similar ones resound from a large chorus of voices that were raised in protest against governmental malpractices during those centuries of almost incessant monetary disorders. But some writers who joined that chorus were not theoretical metallists. To quote an example, François Grimaudet (*Des Monnoyes*, 1576), though he insists that the nominal value of a coin should not surpass the value of the material except for the 'fraiz de façon et quelque petit proffit,' yet states explicitly that the 'essence of money' is in that nominal value *et non en la matière*. On the whole, I think, *valor impositus* should be translated by nominal value, *valor intrinsecus* by value of material, and *valor extrinsecus* by purchasing power (which is, however, also called *potestas*). *Quantitas* also means nominal value, and not quantity. Devaluation is denoted by *mutatio*, *corruptela*, or *augmentum*. The last term corresponds to the English usage of the sixteenth and seventeenth centuries (and even later times) when 'raising' money meant debasement or devaluation.

In that large chorus of protesting voices, I cannot hear any note worth recording. But I shall mention names of a few authors—not all of them scholastics—who seem to have gained considerable contemporary reputation: C. A. Thesaurus' *Tractatus novus et utilis de augmento ac variatione monetarum* (1607), and M. Freher's *De re monetaria* (1605), do display some traces of the distinction between devaluation and depreciation, and may on this account be assigned a special place. Also ran (among many others, doctors and laics): René Budel, Joannes Aquila, Martinus Garratius, Franciscus Curtius, Ioannes Regnandus, Joachimus Mynsinger, Didacus [Diego] Covarruvias (the famous jurist), Henricus Hornannus, Franciscus de Aretio, Joannes Caephalus. There is some difference, partly explained by the fact that they had different situations in mind, in their solutions of the problem of the repayment of debts contracted in a currency that was subsequently debased. This is the problem that really interested the public and is responsible for the unending stream of publications of this kind. But the answers are practical shifts and of no interest for us. One author should be added, however, because his argument on usury secured him one of those places in the history of economics that remain occupied indefinitely for no other reason than that nobody bothers to revise the occupant's claims. Charles Dumoulin (Carolus Molinaeus, 1500-1566) was a French lawyer of reputation whose *Tractatus commerciorum et usurarum redituumque pecunia costitutorum & monetarum* (I have used the 1st ed., 1546) was a great success and enjoyed international reputation. There is nothing in it, however, that could be described as a new contribution to economic analysis.

English 'classics' of the nineteenth century, we have here another of those curious doctrinal affinities that exist between J. S. Mill and Father Molina. Third, we note for future reference that some of the doctors, among whom Mercado is the most important instance, adumbrated more or less clearly what came to be called the quantity theory of money, at least in the sense in which Bodin can be said to have held it. And, fourth, they dealt with a number of problems in coinage,[27] foreign exchange, international gold and silver movements, bimetallism, and credit in a manner that would merit more attention and that compares favorably in some points with much later performance.

Contrary to an opinion that has some adherents, the scholastic doctors did not work out any theory of the physical aspect of production ('real capital'), though they did eventually—since St. Antonine—block out a theory of the role in production and commerce of monetary capital. Nor did they possess any integrated theory of distribution, that is to say, they failed to apply their embryonic demand-supply apparatus to the process of income formation as a whole. Moreover, the rent of land and the wages of labor had not as yet become analytic problems to them. In the case of rent, this was perhaps due to the facts that, with farmers who tilled their own soil, the element of rent does not readily display its distinctive character, and that rents paid to landlords were in the times of the doctors so mixed with dues of a different nature that the economic rent, which was moreover traditionally fixed, did not show up very distinctly even in this case. In the case of wages, too, they did not ask the theoretical question; presumably they felt that nobody needs to be told what it is wages are paid for. They proffered indeed moral considerations and recommendations as to policy. However, even St. Antonine's recommendations, noteworthy because of the broad social sympathies that inspired them, do not rest on any analytic foundations of the kind we are interested in. The same applies to the considerable literature that developed in the sixteenth century on relief of the poor, unemployment, mendicancy, and the like, to which the doctors contributed copiously.[28] Much more important were their contributions to the theories of the two types of income that they did feel to be analytic problems, business profits and interest. The risk-effort theory of business profit is undoubtedly due to them. In particular, it may be mentioned that de Lugo—following a suggestion of St. Thomas—described business profits as 'a kind of wage' for a social service. No less certain is it that they launched the theory of interest.

So far, our sketch of scholastic economics has been drawn without much attention to its methodological philosophy, which will be discussed in the next section, and also without much attention to the logical processes involved in unwrapping the analytic element in the reasoning of the doctors from the normative considerations in which it was embedded. In order to exhibit these processes and to show precisely how it was that they came to ask the question which they were the first to ask—namely, *the question why interest is actually paid—we shall, in the case of interest, be more careful in doing the unwrapping.*

---

[27] The eminence of Copernicus in other fields suggests special notice of his *Monetae cudendae ratio* (1526).

[28] De Soto's *Deliberacion en la causa de los pobres* (1545), and Juan de Medina's *De la orden que . . . se ha puesta en la limosna . . .* (1545), are examples of those scholastic contributions. The subject will be briefly mentioned again (see below, ch. 5).

The motive of scholastic analysis was manifestly not pure scientific curiosity but the desire to understand what they were called upon to judge from a moral standpoint.[29] When the modern economist speaks of 'value judgments,' he refers to moral or cultural appraisal of institutions. As we have seen, the scholastic doctors also passed value judgments of this kind. Primarily, however, and so far as their practical task was concerned, it was not the merits or demerits of institutions that mattered to them, but the merits or demerits of individual behavior within the frame of given institutions and conditions. More than anything else, they were directors of individual consciences or, rather, teachers of directors of individual consciences. They wrote for many purposes but principally for the instruction of confessors. In the first instance, therefore, they had to expound moral precepts that were immutable on principle. Secondly, they had to teach the application of these precepts to individual cases arising in an almost infinite variety of circumstances.[30] But this was not enough. In order to secure something approaching uniformity of practice among the numerous confessors, it was necessary to work out concrete decisions for the more important types of cases that occur in practice. Moreover, one of the considerations that are most helpful in deciding whether, from the standpoint of a given individual, a given act is a sin, and if so, how serious a sin it is, is whether or not it is common practice in the individual's environment. For both these reasons it was necessary for the doctors to investigate typical forms of economic behavior and also the actual practices prevailing in the environments under their observation—a task that was often so simple as not to call for special effort, but was exceedingly difficult when it came to the complex phenomenon of interest.

Thus the normative motive, so often the enemy of patient analytic work, in this instance both set the task and supplied the method for the scholastic analysts. Once set, the task was strictly scientific and logically independent of the moral theology whose purposes were to be served. And the method was also strictly scientific: in particular, it was eminently realistic, since it involved nothing beyond observation of facts and their interpretation: it was a method of working out general principles from 'cases' somewhat akin to the method of English jurisprudence. Moral theology came in only after the analytic work was done in each case, to subsume the result under one of its rules.

---

[29] For our purpose, the history of legislation on interest, whether proceeding from temporal or spiritual authority, is not of any great importance. Moreover, the reader will find in the *Encyclopaedia of the Social Sciences* or in *Palgrave's Dictionary* all he may wish to have in the way of general orientation. Nevertheless, a few facts about the policy of the Catholic Church may be welcome at this point. In the times of the Roman Empire the Catholic Church dealt very cautiously with interest, Aristotle and St. Luke notwithstanding. The Council of Nicaea (325) did not go beyond a prohibition addressed to the clergy, though more general disapproval was expressed. The decisive step, which also included the declaration that secular legislation to the contrary was invalid (St. Thomas had not thought so), was not taken until 1311. Prohibition was then reaffirmed many times and is still in force. But its practical importance decreased along with the decrease in importance of the cases that came under it, as will be explained in the text. Some notice of this was eventually taken in the encyclical *Vix pervenit*, 1745. In 1838 a circular instructed confessors not to disturb penitents who accept interest at current rates.

[30] The theory of this was given, e.g., by St. Thomas (*Summa* II, I, quaest. VII). The chief reference, so far as moral theology is concerned, for what follows in the text is to St. Alphonso de'Liguori (1696-1787; *Theologia moralis*, see *Works*, English ed., 1887-95.)

It is not surprising, however, that to unsympathetic critics of scholastic work, scholastic research into interest appeared in the light not only of 'casuistry' in a derogatory sense of the term but even of a series of attempts to cover the retreat of the Catholic Church from an untenable position by logical tricks or subterfuges, and to justify *ex post* each *fait accompli*. The reader may judge for himself. But it is as well to point out a fact that will seem to support that opinion. On the one hand, moral precept, however immutable, will yield different results if applied to different circumstances; and capitalist evolution did create circumstances in which the cases that came under the prohibition of usury rapidly decreased in importance. On the other hand, such an evolution will be inevitably paralleled by subterfuges of interested parties, who will try to avail themselves of all the possibilities offered by a system of rules and exceptions that grew increasingly complex; perhaps the most famous of these subterfuges was the abuse of the element of *mora* presently to be mentioned in the text, but there were many of them. This parallelism cannot fail to impress the superficial observer, particularly if he is not very well versed in either scholastic literature or economic theory. Moreover, we are speaking of scholastic doctrine at its highest. It is of course not denied that the ordinary clerical practitioners, like any bureaucracy, committed a great many mistakes and fostered resort to subterfuges both by unintelligently restrictive interpretation of the rules they were directed to apply and by well-meaning connivance at evasions.

Usury, then, was sinful. But what is usury? On the one hand, it does not necessarily involve the exploitation of the needy: this element is morally relevant in other respects but was not a constituent of the scholastic concept of usury. On the other hand, usury is not always present when more than repayment of the sum lent is stipulated: simple exegesis of St. Thomas' teaching sufficed to justify compensation for the lender's risk or trouble—particularly evident in the purchase below par of notes—or compensation in cases where the lender was deprived of his money against his will, as in cases of forced loans, or of the debtor's failure to repay at the stipulated time (*more debitoris*). Thomistic teaching even suggested Molina's proposition that, since the lender of any commodity is in any case entitled to receive back its full value at the time of lending, more units might have to be repaid than were given (*esto plus in quantitate sit accipiendum*), though no application was made of this, so far as I know, to money loans. From all those cases emerged the principle that a charge was to be considered as normal or unobjectionable whenever the lender incurred any loss (*damnum emergens*). Some doctors argued that the lender in temporarily giving away his money always and inevitably suffers such loss. But most of them refused to accept this view. Nor did the majority admit that the gain the lender foregoes by lending (*lucrum cessans*) is in itself a justification for making a charge. They did admit, however, that, as we may put it, gain foregone turns into actual loss when the opportunity for such gain is part of a man's normal environment. This meant two things. First, merchants themselves who hold money for business purposes, evaluating this money with reference to expected gains, were considered justified in charging interest both on outright loans and in cases of deferred payment for commodities. Second, if the opportunity of gain contingent on the possession of money is quite general or, in other words, if there is a money market, then everyone, even if not in business himself, may accept the interest determined by the market mechanism. This proposition had to be handled with care, for it evidently opened the door to all sorts of evasions. But it is no more than a special case of the principle that everyone may, in justice, pay and ask the current price for everything, and was not invented ad hoc: if it is not in evidence in the thirteenth century and much in evidence in the sixteenth, this is merely due to the fact that money markets had been uncommon in the former century and became quite common in the latter.[31] Observe that whenever alternative opportunities of gain are normally available to everyone, the argument from gain foregone will coincide with the argument from 'privation': foregoing gain is in this case precisely what the privation consists in. Observe further that in *all* the cases mentioned justification rests on circumstances that, however frequently or even generally they may prevail in a given environment, are logically accidental to the pure loan contract (*mutuum*), which in itself was never held to justify interest. And observe finally that justification was never, or hardly ever, based upon the advantages that the *borrower* might reap from the loan: it was exclusively based on the disadvantages that lending brought to the *lender*.

Dropping now the normative garb of scholastic interest analysis and the moral *doctrines* that motivated their research, we may restate as follows the causal *theories* their research unearthed, on the understanding that the picture cannot be quite satisfactory because the scholastic doctors did not much more agree on the theory of interest than do we.

1. Interest, though construed on the more general model of loans of 'con-

---

[31] This is no doubt a very imperfect account of a rich doctrinal development. Considerations of space, however, make it impossible to present a more satisfactory one which the interested reader will find in Professor Dempsey's book. Also see A. M. Knoll, *Der Zins in der Scholastik* (1933). But a much discussed construction, associated with the name of the famous Dr. Eck (1486-1543) and also favored by Navarrus and Major, should be noticed, the triple contract, *contractus trinus*. It is, of course, licit to enter into a partnership and to draw an income from it. Nothing prevents the partner in a business from insuring his capital against loss; hence he may also do so with his other partners in which case the price of the insurance will amount to a reduction of his share in the profits. Finally, he may legally convert this reduced share in variable profits into a constant annuity that will represent pure interest. This construction is interesting from an analytic point of view because it exhibits the connection between interest and business profits in a very instructive way. As a defense of usury it was, however, rightly condemned. For either we accept the argument that the partner in question has alternative business opportunities of the kind that justify the charging of interest; then the construction is superfluous. Or we do not accept that argument; then the failure of the second contract to reduce that partner's share to zero (apart from a remuneration of his work) would spell usury. The logical slip involved in Eck's argument is worthy of the reader's attention.

sumptibles,' is essentially a monetary phenomenon. There was no analytic merit in this. The scholastic doctors simply accepted a surface fact exactly as had Aristotle. They did sometimes relate interest on money to the returns of income-bearing goods, land, mining rights, and the like that may be bought for money. But this point—though used in some interest theories of the seventeenth and eighteenth centuries—was without analytical value because the price of income-bearing goods and therefore the net return from them already presupposes the existence of interest.

II. Interest is an element of the price of money. Calling it a price for the use of money does not explain anything and at best restates the problem in an unenlightening way. In itself, it is an empty phrase. Nor is the analogy of interest with interlocal premia or discounts on money more than a restatement of the problem. For these interlocal premia and discounts are explained by risks and costs of transfers whereas pure interest, as distinguished from compensation for risks and costs, is an intertemporal premium which the analogy does not help to explain. The uncritical appeal to mere lapse of time per se is valueless—circumstances are easily conceivable in which it would fail to produce a deviation from zero interest. Though negative only, these propositions are of great analytical value. They clear the ground and prove that the scholastic doctors—in this respect much superior to nine-tenths of the interest analysts of the nineteenth century—saw the real logical problem involved. In fact, these propositions define it. This is why they should be credited with having launched the theory of interest.

III. Hence deviation of interest from zero is a problem the solution of which can be found only by analysis of the particular circumstances that account for the emergence of a positive rate of interest. Such analysis reveals that the fundamental factor that raises interest above zero is the prevalence of business profit—all the other facts that may produce the same results are not necessarily inherent in the capitalist process. This proposition constitutes the main positive contribution of scholastic interest analysis. Adumbrated before, it was first clearly stated by St. Antonine, who explained that though the circulating coin might be sterile, money capital is not so because command of it is a condition for embarking upon business.[32] Molina and his contemporaries, while rightly insisting that money was 'in itself' not productive and no factor of production, yet accepted a similar view: they coined the significant phrase that money was the Merchant's Tool. Moreover, they quite understood the mechanism by which this premium, if capitalist business be sufficiently active and—relative to the rest of the environment—sufficiently important, will tend to become an all-pervading normal phenomenon. And their ideas on *lucrum cessans* and *damnum emergens* complement their analysis as regards the supply side of the money market.

---

[32] This, of course, was a frontal attack on Aristotle's 'sterility of money.' It is interesting to note that St. Thomas' argument proffered a clue for this. After having taught that there was no reason why money should ordinarily carry a premium, he went on to say that there were secondary employments of money in which something might be charged for it. This would be the case, for instance, if somebody lent money for the purpose of enabling the borrower to deposit it as a pledge or guarantee (*loco pignoris*). St. Thomas certainly did not mean to include business loans in these 'secondary uses,' of money. But this was done in Jacobus Ferrarius' *Digressio resolutoria* . . . (1623), where the author went so far as to include all loans made for any legitimate purposes whatsoever.

Further than this they did not go. Their theory of business profits in particular was not sufficiently developed to allow them to reap the full benefit from the insight that led them to trace interest to profit as its source. Also, being the first in this field, they groped for their generalizations rather than stated them. In this prolonged process of groping they slipped up frequently and used many inadequate and even faulty arguments. But if we are to treat them as we treat other groups of analytic workers, merits prevail greatly over shortcomings, especially if we give them credit, as we ought to, for much of what successors and even opponents learned from their analysis.

But what, if that be so, becomes of the great battle on interest between scholastic and anti-scholastic writers that is supposed to have raged in the sixteenth and seventeenth centuries? So far as the history of economic analysis is concerned, the only answer is that there was no battle. No analytic progress was made and no new analytic ideas on interest were proffered for a long time to come. Even the most famous leaders on the anti-scholastic side such as Molinaeus or Salmasius[33] had nothing new to say: Molinaeus and Navarrus—contemporaries roughly speaking—were about on a par in theoretical grasp of the interest problem. Salmasius only reformulated the scholastic theory about *lucrum cessans* from available business opportunities that we find in Molina. So far as the moral issue was concerned, the Protestant theologians and the laic lawyers differed among themselves on the subject of interest, but were also content to repeat arguments forged by the scholastics, whichever side they espoused.[34] But, in addition there was a legislative or administrative issue, and it is this that accounts for the controversy in question. As we have seen, the scholastics held that interest had to be justified on grounds not inherent in the loan contract (*mutuum*) as such. But this amounted to saying that each case, or at least each type of case, was on trial and not to be approved without investigation. Though they did not always object to secular legislation that permitted interest,[35] it is easy to imagine what inconvenience this principle must have caused after interest had become a normal phenomenon. The question naturally arose, that was in the end answered affirmatively by Popes Pius VIII and Gregory XVI, whether in such circumstances an overcomplicated set of rules, however correct logically, should not be replaced by admitting a sweeping presumption that the acceptance of a market rate of interest was all right. This is really all that a steadily increasing number of laical and even clerical writers demanded. But they did not put it this way, partly because they were not able to understand the finely spun logic of the scholastics and therefore set it down as mere sophistry, and partly because, most of them being enemies of the Catholic Church or the scholastic doctors for political and religious reasons, they could not bring themselves to argue the question of policy without sneers or invective. This created the impression that there was a battle between old and new *theoretical* principles which, since it distorts the picture of a phase in the history of economic analysis, it seemed worth while to dispel.

---

[33] Molinaeus (Charles Dumoulin) has been discussed above. Salmasius (Claude de Saumaise, 1588-1653) wrote a number of tracts on interest, of which it is sufficient to mention two: *De usuris* (1638; but there seems to have been a previous ed., 1630) and *De foenore trapezitico* (1640).

[34] We may as well dispose of this matter once for all. Scholastic doctrine was taught by Richard Baxter (1615-91; see, e.g., his *Christian Directory*). On a lower level, the same holds for the considerable literature on interest that, representing the popular reaction to the financial aspects of rising capitalism, denounced usury on purely moral grounds. Here are a few English samples which, I think, are fairly representative: Thomas Wilson, *Discourse upon Usurie* (1584, but there was an earlier ed., in 1572, according to the Kress Library Catalogue; new ed., with introduction by R. H. Tawney, 1925). Philippus Caesar, *General Discourse against the Damnable Sect of Usurers* (1578), purely moral invective; Anon., *Death of Usury or the Disgrace of Usurers . . .* (1594); Anon., *Usurie Arraigned and Condemned* (1625). There were, of course, plenty of sermons that I have not investigated. Roger Fenton (*Treatise of Usurie*, 1612) may stand for the defense of interest on a ground that was known to the scholastics but not accepted by them as relevant to the *moral* issue, viz. the advantage that accrues to the borrower.

5. The Concept of Natural Law [1]

We must now attend to a subject the consideration of which we have twice deferred. It is beset with difficulties and an inexhaustible source of misunderstandings which cannot be straightened out entirely in the available space. An appeal for the patient co-operation of the reader is, however, justified by its fundamental importance for the origins and early history of all social sciences. For the first discovery of every science is the discovery of itself. Awareness of the presence of a set of interrelated phenomena that give rise to 'problems' is evidently the prerequisite of all analytic effort. And in the case of the social sciences, this awareness shaped itself in the concept of natural law. We shall try to disentangle its various meanings and to catch their subtle changes and associations.

---

[35] St. Thomas even went so far as to say (loc. cit. *ad tertium*) that, in the condition of imperfect man, many useful things would be impeded (*multae utilitates impedirentur*) if all sins were strictly forbidden by human law.

[1] From the large literature on the subject, I select for the reader's general information Sir Frederick Pollock's 'History of the Law of Nature' (in his *Essays in the Law*, republ. 1922). Also see P. Struve, 'L'Idée de loi naturelle dans la science économique,' *Revue d'économie politique*, July 1921. The only study I can commend for correct appraisal of the work done under the auspices of the natural-law idea (though of the work of the successors of the scholastics rather than of the scholastics themselves) is O. H. Taylor's 'Economics and the Idea of Natural Laws,' *Quarterly Journal of Economics*, November 1929. Vinogradoff's well-known *Outlines of Historical Jurisprudence* (1920-22) may prove helpful.

(a) *The Ethico-Legal Concept.* The scholastic doctors themselves traced their concept of natural law back to Aristotle and the Roman jurists, although, as we shall presently see, they made of it something totally different. Aristotle, speaking of justice, distinguished the 'naturally just' (φυσικὸν δίκαιον) from the 'institutionally just' (νομικὸν δίκαιον) (*Ethics* v, 7). But in that passage, the term Natural must be understood in a very narrow sense. Aristotle there means to refer only to forms of behavior that are enforced by very general necessities of life that man shares with other animals. But elsewhere he used the term Natural in a much wider sense, in fact in all the senses it ever acquired without distinguishing, let alone defining, them clearly. And the Natural in the wider senses, also, he associated with the Just, thus setting an example for ages to come—even the English 'classical' economists sometimes mixed up the natural and the just—though he was not quite consistent about it: he sometimes approved of what he did not call natural; but he never disapproved of anything to which he affixed this label.

The Romans, not much given to philosophizing, simply accepted the Aristotelian definition: Gaius (*Instit.* I, 2) said naïvely that natural law (*jus naturale*) 'is what nature has taught all animals' (*quod natura omnia animalia docuit*). Ulpian said the same thing. They simply accepted this Natural Law as a source of legal rules that was just as good as, and in fact superior to, any of the sources of positive law, statutory and other. But there are two important points to be noticed in addition. First, there developed a tendency among Romans of literary propensities, such as Cicero, to affix the term *jus naturale* to what was officially called *jus gentium*. The reason was that the latter, embodying as it did rules of equity, seemed somehow more 'natural' than the formalistic civil law. The reader should observe that this sense of natural law, the sense that ultimately prevailed (while, as we have seen, the term *jus gentium* acquired in the seventeenth century the meaning of Law of Nations) is not identical with the sense defined by Aristotle in *Ethics* v, 7, though it has more to do with the other senses in which Aristotle actually used the word Natural. Second, the Roman jurists also associated different meanings with the words Nature and Natural, of which one is important for us:[2] the *rei natura* or the nature of the case. For instance, when we are confronted by a legal question arising out of a contract, we must first find out what the 'nature of the business' was that the parties to the contract intended to effect. At first sight, this nature of the case seems to have nothing to do with natural law in any sense—as many legal treatises try to explain that are written by jurists who, under the influence of the historical school, have come to hate the very phrase Natural Law. But we shall presently see that it has a lot to do with it.

St. Thomas[3] accepted the Aristotelian definition in the legalist formulation of the Roman jurists but merely as a matter of form. Actually, his attempt to put logical order into Aristotle's various uses of it produced something that was neither Aristotelian nor Roman.[4] In the first place, natural law or the 'naturally just' (*lex naturalis, justum naturale*) may be the set of rules that nature imposes upon all animals and also may be, in the sense of Aristotle's definition, immutable on principle. But since these rules work out differently in different conditions of time and place and with different people, and since it is possible to add to them or to subtract from them, even this natural law became historically variable in practice (see, especially, *Summa* II, 1, quaest. XCIV, art. 4 and 5). In the second place, there was another meaning of natural law that St. Thomas explains only by examples but which really equates natural law to the set of rules that conform (*habet quandam commensurationem*) to social necessity or expedience, the historical relativity of which St. Thomas never tired of stressing. Natural law in *this* sense is almost, though not quite, identified with *jus gentium* in the Roman official sense. In the third place, it is held that human positive law necessarily consists either in deductions from this natural law or in adjustments of its rules to particular conditions. An enactment that violates any rule of *this* natural law does not make valid law at all. The reader will notice the political implications of this doctrine.

---

[2] Other meanings are embodied in such terms as *naturale negotii* and *naturalis obligatio* with which I do not want to bother the reader. All of these and other meanings, though distinct, are of course related.

[3] What may be termed the Thomistic theory of law, natural and positive, is presented in *Summa* II, 1, quaest. XCIV, XCV, and XCVII; II, 2, quaest. LVII, art. 2 and 3. Interpretation is not easy. My thesis of the mutability of natural law is gleaned from

To make a long story short, we leap from St. Thomas to Molina. Molina clearly identified natural law, on the one hand, with the dictates of reason (*ratio recta*), and with what is socially expedient or necessary (*expediens et necessarium*), on the other. These propositions, in themselves, are nothing but Thomism formulated more pointedly. But he took a further step (*tract.* I, *disp.* 4): after repeating the Aristotelian definition he added, apparently by way of explaining its meaning: 'that is to say,' the naturally just is that which obligates us by virtue of the nature of the case (*cuius obligatio oritur ex natura rei*). But this is not at all what Aristotle meant. Molina does not interpret his meaning but adds a new one: he definitely married natural law to our rational diagnosis, with reference to the Common Good, of the cases—whether individual contracts or social institutions—which we observe in research or practice. Molina's

---

an argument that purports to prove the contrary but so qualifies and hedges in the principle that the subsequent statement in the text seems warranted. St. Thomas also argued that natural law was the same *apud omnes* and again the practical upshot is relativity: his emphasis upon what is *loco temporique conveniens* suffices to establish this, though different interpretations may very well be appropriate from philosophical or theological standpoints.

[4] Many critics will disagree. They will point to the references to Aristotle and Ulpian by which St. Thomas supported his exposition. Very likely, these critics and I will have to agree to differ, because no agreement can be expected in matters into which the personal equation of interpreters must inevitably enter. The personal equation in this case refers to the importance we attach to passing remarks, *obiter dicta*, hints. I admit that pointers to St Thomas' teaching can be found in Aristotle and the Roman jurists (also in Cicero). But their weight appears to be so great only because it is precisely such passages that St. Thomas brought together. Taken independently of what he made of them they amount to very little.

view about 'the nature of natural law' is mentioned only as an example of what was the general opinion of the doctors in his and even an earlier time. De Soto's concept of the Command of Reason (*rationis ordinatio*) amounts to the same thing.

One way of putting this result is to say that all speculative or metaphysical or non empirical elements had evaporated from Molina's natural-law concept, and that there was nothing left but reason applied to particular facts, though, so far, applied from the normative standpoint. Unfortunately, however, the subject is more complicated than this. The doctrine of the scholastics also contains the sources of two currents of thought that are the very opposites of sober matter-of-factness. These must be mentioned because they contributed substantially to the prevailing confusion about natural law. First, there is the association of natural law with primitive conditions. We have seen that, following Aristotle, the doctors, like A. Smith, frequently made use of a pseudo-historical method of exposition: they liked to start, in explaining a social phenomenon such as property or money, from an imaginary 'early state' of society. They did not, so far as I can see, make any improper use of this construction. But the Natural was the Just and if the Natural is particularly clearly revealed in primitive conditions, as that method of exposition implies, then primitive conditions become just as well as natural. From this standpoint starts an uninterrupted line that runs right into Rousseau's glorification of the natural, in the sense of primitive, state of humanity—an association that is entirely immaterial but did not add to the standing of the concept. The scholastics themselves, needless to say, displayed no tendency to glorify primitive conditions.

Second, there is a relation between the scholastic natural law and the Rights of Man, *droits de l'homme*, and similar eighteenth century constructs including the laborer's natural right to his product. The existence of this relation cannot be doubted. For the natural law of the doctors was considered as a source of valid legal rules about rights and duties, and all the framers of the *droits de l'homme* pretended to do was to draw on this source for the Command of Reason or *rationis ordinatio* with respect to the political rights of civilized man. Moreover, some items in the list of these rights are clearly recognized by scholastic writers. And yet, the speculative character of these and similarly conceived rights is a commonplace. It is precisely this sort of thing, more than anything else, which accounts for the distaste many of the best economists have felt for the concept of natural law, and which has made it a byword for unhistoric and unscientific metaphysics. So much is this the case that, with some of us, a proposition need only be linked up with natural law in order to be put out of court; in fact, one of the most common reasons for wholesale rejection of economic theory to this day is that it is nothing but an offshoot of unscientific natural-law philosophies. We have, therefore, every motive for looking more closely at the indictment. This will be done under the next heading.

(b) *The Analytic Concept.* So far we have been inquiring into the development of the natural-law concept in its role within the ethical and legal sphere or, what amounts to the same thing, of natural law considered as a source of morally and legally valid imperatives. After what has been said in preceding sections of this chapter, it is easy to find the bridge to the natural-law concept in its analytic role. In fact, we need only generalize our findings in the special case of the theory of interest. For this purpose, let us ask the question: why should Aristotle have called certain forms of behavior 'naturally just' in the narrow sense of his definition? Evidently because these forms of behavior were necessary conditions of the survival of (as he thought) animal life in general. A similar answer will hold true for the 'naturally just' in the wider sense that covers the necessities of social life in the actual historical circumstances of any given human society. Therefore, in order to find out what is naturally just in any particular case, it is first necessary to analyze these circumstances. The generalizations that we may derive by so doing can be called natural law in the analytic sense: *the normative natural law presupposes an explanatory natural law*. The former is nothing but a particular kind of value judgment passed upon the facts and the relations between facts unearthed by the latter. The two are logically as distinct and practically as distinguishable as are the value judgments and analytic propositions of any economist. For instance, A. Smith had a theory of wages that consists of statements of fact and of generalizations derived from them. But he also said (*Wealth*, Bk. I, ch. 8) that 'the produce of labour constitutes the natural recompence or wages of labour.' Since by produce of labor he there meant the whole product, and since, on his own showing, the wages do not normally amount to that, we have here clearly a natural-law proposition in the philosophical or value-judgment sense. But when we are interested in scientific analysis only, we have no difficulty in discarding this sentence. Or, a modern economist may both analyze the phenomenon of price discrimination and pass a value judgment upon it. If he does the latter by calling it unjust, he is adopting a natural-law rule that does not differ, in this case, from that of the scholastics. If he approves of the Robinson-Patman Act, which forbids discrimination, he does what the scholastics would have done in their day by saying that this act is valid law because it conforms to an imperative of natural law. We may indeed call this, or any value judgment of any kind, unscientific or extrascientific. But there is no point in throwing out the analytic baby with the philosophic bath-water. And this is precisely what is being done by those who dispose of the economics of the scholastic doctors or their laical successors merely by pointing to its associations with a system of moral and legal imperatives—of natural laws in the analytic sense because of its association with a system of natural laws in the normative sense.

The main objection raised against natural-law jurisprudence and economics by the historical school was, however, not this but a different though related one: natural law was supposed to be entirely divorced from historic reality. We have seen that this objection is unfounded so far as the scholastic doctors, who always stressed the historical relativity of social phenomena, are concerned. It is better founded in the case of some of their successors. But it should be observed that, whether well or ill founded, this objection touches only the use of the concept and not the concept itself. Any concept can be faultily used. Moreover, any theory may be inadequate or wrong. In particular, it may claim for its propositions an undue amount of generality. The theoretical views associated with the *droits de l'homme*, for instance, certainly did. But an inadequate—or even wrong—scientific theory is still a scientific theory. On the other hand, we shall understand that the absolute claims made in the eighteenth century on behalf of certain legislative programs, without due reference to conditions of time and place, fostered all sorts of misunderstandings of the true character of natural-law analysis.

I have said that social science discovered itself in the concept of natural law. This will be particularly clear if we visualize it in the form of Molina's definition—as distilled from the 'nature of the case,' the *rei natura*. Taken in this sense, the ideal of natural law embodies the discovery that the data of a social situation determine—in the most favorable case, uniquely—a certain sequence of events, a logically coherent process or state, or *would do so if they were allowed to work themselves out without further disturbance*. This is putting it in modern terms. But the reason why we may attribute this idea, in however rudimentary a form, to the scholastic doctors is in their concept of justice. This (Aristotelian) concept of justice St. Thomas explained by relating the word 'justice' to adjustment and the word 'just' to adjusted. Just is what is adjusted, or conforms, to—what? The only answer we can give if we take the clue proffered by Molina's *rei natura* is: to the social pattern involved, as viewed from a utilitarian Common Good or social expediency. Hence the equations between just and natural, natural and normal.[5] Hence also the ease with which *they* passed from normative doctrine to the analytic theorem and vice versa, and with which *we* can pass, for example, from their just price to the price of (short- or long-run) competitive equilibrium. Hence, finally, the relation—not, of course, amounting to identification—that subsists with them between justification and explanation. Therefore, while it is true, as a matter of history, that modern economics stems from the scholastic writers, as its critics hold, it is also true that this fact does not constitute an objection.[6]

---

[5] This relation between natural in the sense of normal and natural in the sense of just explains why the term Natural survived so long—almost until Marshall—in the former sense and also why some authors, who had certain philosophical ideas about 'natural liberty,' continued to link it with the just. But this is not all of it. The proviso about absence of disturbance that occurs in our text a few sentences earlier indicates a somewhat different but related meaning of such phrases as natural prices, natural wages, and so on: in these phrases Natural simply means that disturbances other than such as may have been included in the data are assumed to be absent, or that we intend to investigate a process or state as it would be if left to itself. Also, it is, of course, absurd to look for natural-law philosophies wherever the word Natural occurs: 'naturally' in particular simply means the same as 'obviously.' We do not commit ourselves to any philosophy when we state that a man is 'naturally' offended after having been called a fool. It seems worth while adding that the term Normal must not be understood in the statistical sense but rather in the sense in which we speak of normal eyesight: a physiologist, from his grasp of the *rei natura*, in this case of the structure of the human eye, may arrive at a concept of normality that may be far removed from any statistical measure of the actual eyesights observable in any given population.

(c) *Natural Law and Sociological Rationalism.* I. *A comment on philosophical rationalism.* In order to exhibit a point that is important for us, we select the following meaning of the protean word Rationalism. We call Philosophical Rationalism the belief not only that our mind ('natural reason') is the source of truths that are antecedent to experience, but also that our mind is able to produce results about supermundane subjects, such as the existence of God.[7] In this sense, St. Thomas was a metaphysical rationalist because, unlike other (mainly Scotist) scholastics, he believed that the existence of God can be logically proved. He was not a metaphysical rationalist in the sense in which this phrase came to be used in the seventeenth and eighteenth centuries, namely, that human reason was the *only* admissible source of knowledge in matters of theology, for he also admitted revelation. Now, if a man believes that, also by the unaided powers of his own logical apparatus, he can prove that God does not exist, he is indeed, in this particular matter, contradictorily opposed to St. Thomas. But there is a point in which they are nevertheless brothers in the spirit: the rationalist deist and the rationalist atheist are both rationalists in the sense defined and allies against anyone who does not trust his reason to soar as high as that, in particular against any logical positivist of today. Of course, there is nothing surprising in this. It is a most common occurrence that people who hold different views, nevertheless recognize, and appeal to, the same authority. But it was necessary to advert to this fact because it will help us to see continuity in doctrinal development where, without its help, we should see nothing but break and antagonism.

II. *Sociological rationalism.* Scientific activity is often looked upon as the standard instance of rational activity in the sense that the worker, whatever his ultimate aim, allows himself to be guided by the rules of logical inference. This is indeed not quite accurate: precisely the strongest achievements in science proceed not from observation or experimentation and orderly logic-chopping but from something that is best called vision and is akin to artistic creation. Still, results have to be 'proved' by the logical or rational procedure dictated by professional standards and this suffices to impress rationality in this sense—which has nothing to do with the sense discussed above—upon the stock of scientific knowledge that we possess at any time. But this concept of scientific rationality refers only to the attitude of the analysts and not to the behavior of the object analyzed. The alienist may 'rationally' investigate the reactions of madmen, the sociologist may rationally investigate war psychologies or the behavior of maddened crowds, without implying that the words and actions observed 'make sense.' So far as this goes, we are all of us, including the scholastic doctors no less than their worst enemies, of necessity Methodological Rationalists, that is, we all believe that *some* rational methods are applicable to the description of social phenomena. Generalizations resulting from the application of such methods may be called natural laws, and this is the only *indispensable* relation that exists between the natural-law concept and the 'right reason' or *ratio recta.*

---

[6] Some historians of economics have believed that the normative element acquired added significance owing to its theological nature (observe, by the way, the meaning of 'nature' in this sentence). This has been held to be relevant even for an appraisal of the physiocrat system (see below, ch. 4, sec. 3). This, however, is another error. For the scholastic order of things, physical and social, is entirely autonomous within the scholastic theology, the only influence of which—beyond ethical imperatives—concerns the problems of miracles and of creation. Apart from miracles and creation, this order is to be understood entirely by the light of human reason. No doubt, in analyzing it, reason is analyzing part of God's works. But since God's plan in any case includes any amount of 'evil,' not even evaluation is seriously restricted by association with theology, and analysis is left entirely free. For discussion of an exactly opposite error of interpretation, see the next section.

[7] I have to apologize for the innumerable shortcomings of this definition. It is, however, brief and it is sufficient for the purpose of making the one point that is relevant to our subject.

But Sociological or Economic Rationalism means something else. Just as we may look upon the physical universe—in the way first made fashionable by the Stoics—as a logically consistent whole that is modeled upon an orderly plan —so we may look upon society as a cosmos that is possessed of *inherent* logical consistency. For us, it matters little whether this order is imposed upon it by divine will—directed to some definite ends by an invisible hand—or is inherent merely in the sense that the observer discovers in it plan and purpose that are independent of his analytic rationality, because in either case nothing is allowed to enter that 'rational' cosmos but what comes within the grasp of the light of reason. We must, however, further distinguish Objective Sociological or Economic Rationalism which does not, and Subjective Sociological Rationalism which does, postulate that this order or plan is or can be realized by the rational action of the individuals or groups that compose society. Both must evidently be attributed to the scholastic doctors as well as to most of their successors down to our own time. And this lends additional color to their concept of Natural Law and establishes another relation between it and their *ratio recta* that is quite distinct from the one established in the preceding paragraph—the relation formulated for all times by St. Thomas: *rationis autem prima regula est lex naturae* (*Summa*, II, 1, quaest. XCV, art. 2).

This, of course, is inacceptable from the standpoint of modern positivism. It constitutes in fact the one justification for finding 'speculation' not only in the normative but also in the analytic concept of natural law. All the more important is it to repeat that sociological or economic rationalism bears only upon the interpretation of natural-law propositions and not necessarily upon their content. We may drop the former and retain the latter. It is true, however, that the postulate of subjective rationalism embodies an exaggerated opinion of the explanatory value of rational action and tempts us into placing undue confidence in teleological arguments and into similar errors. This is especially serious if associated with a habit economists have of setting themselves up as judges of the rationality not only of means but of ends (motives), that is to say, if they approve, as rational, of ends (motives) that seem 'reasonable' to themselves and dispose of all others as irrational. The scholastic doctors are guilty on all these counts. But it is interesting to note that so are we: in this respect, too, as in so many others, we are their heirs. No better example can be found to illustrate this point than Alfred Marshall.

III. *Ratio recta* and *la raison*. Observe that sociological or economic rationalism need not lead to 'conservative' attitudes in practice. Like metaphysical rationalism it cuts both ways. We may indeed infer from our belief in the existence of an economic order or cosmos that all is always for the best in the world as it actually is—the view that Voltaire ridiculed in the figure of Dr. Pangloss (in *Candide*). But we need not assume that the rational order of things actually exists in the things as they are. It is sufficient to believe in a rational order that exists only in the realm of reason and that reason itself calls upon us to assert as against a deviating reality. This is the meaning sociological or economic rationalism carries with all reforming groups who propose 'to apply reason to social phenomena'—with the men of the Enlightenment whose cult of *la raison* was of this type, with the Benthamites, and with most liberals, radicals, and socialists of today. *And all of them descend from the scholastics.* For the political sociology of the doctors is by itself sufficient to prove that they held the second and not the first view concerning the social cosmos or the natural law. All the differences in the results of the application of the 'light of reason'—amply accounted for as they are by differences of standpoints and circumstances—are immaterial so far as the point under discussion is concerned. It is the same methodological principle that pervades all sociological and political thought that is not anti-intellectualist. The Greeks were the first to give it articulate expression. But the scholastics were the first to do so in the Germanic world. Whatever *la raison* revolted against in the eighteenth century, it was not a mode of thought. Epistemologically, there is perfect continuity, and *ratio recta* (equal to *naturalis ratio*) is the mother of *la raison*.

This need not surprise or shock anybody. The sword that was forged by angels might easily fall into the hand of devils. And the sword that was forged by devils might be wrenched from them by angels—only that, in this case, the devils are entitled to the kind of recognition that every civilized socialist extends to the achievements of capitalism.

6. The Philosophers of Natural Law: Natural-Law Analysis in the Seventeenth Century

We now part company with the scholastic doctors in order to consider the work of their immediate successors. The eternal questions about the government of mankind continued to be asked, of course, and others arose during the seventeenth century from the welter of new political patterns and problems. Especially in England, these produced a torrent of pamphlets of all types that ranged all the way from closely reasoned argument—I suppose that the writings of (George Savile, Marquess of) Halifax, the 'trimmer,' will always stand out as the peak achievements of this literature—to rantings nourished on apocalyptic quotations. But the craving for answers was also satisfied, on the level of general principle, by a group of writers whom we shall call Philosophers of Natural Law.[1]

(a) *The Protestant or Laical Scholastics.* Though separated from the scholastics by the religious split and by the change in the political scene, they were of the same professional type as the scholastics and they went about the same task, by the same method, in much the same spirit—so much so, in fact, that the best way of characterizing them is to call them Protestant (or laical) scholastics. They would not, of course, have agreed with this diagnosis. Nor is the characterization likely to appeal to modern students of either Catholic or Protestant or 'liberal' sympathies. They all emphasize the differences in religious and political beliefs or doctrines and, from their standpoints, are quite right in seeing contrast where we see similarity. It cannot be too often repeated that in this book we are concerned only with the methods and results of analysis and that everything else comes in only so far as it sheds light on them. And these methods and results do not differ substantially from those of the late scholastics. This does not mean that the philosophers of natural law copied the scholastics without saying so. Though in many cases scholastic influence is clear beyond reasonable doubt, there presumably was also rediscovery or development from the same sources—the Roman jurists in particular.

The current of thought that the philosophers sponsored was much too important to leave any educated person untouched. Moreover, as will become clear presently, they were but a link in a sequence that runs far into the nineteenth century. For both reasons it is impossible to speak of them as a definitely delimited group. Just now we shall exclude not only all those authors whom it is usual to appraise as mere economists but also all those contributions that do not bear any relation to the philosophy of natural law, even though the men who wrote them belonged to the group. On this understanding, it will suffice to mention a very few representative seventeenth-century names: Grotius, Hobbes, Locke, Pufendorf.

Hugo Grotius or Huigh de Groot (1583-1645, *De jure belli ac pacis*, 1st ed., 1625; 2nd rev. ed., 1631) was first and last a great jurist whose fame rests upon his outstanding performance in international law. He dealt but briefly with economic subjects, such as prices, monopolies, money, interest, and usury in Book II, ch. 12—very sensibly no doubt but without adding anything of note to the teaching of the late scholastics.

Thomas Hobbes (1588-1679; besides the *Leviathan* (1651), *De cive* (1642) and *De corpore politico* (1650) should be mentioned; Sir Leslie Stephen's biography may be recommended as one of the best sketches of the cultural backgrounds of that time) was an Oxford man of the private-tutor type and, first and last, a political sociologist. He was not more interested in economics than was Grotius, though he also touched upon economic subjects, especially money. His importance for us is due not so much to the powerful originality of his political philosophy (which really fits in better with the subject of the next chapter) but rather to the fact that, more than any other philosopher of natural law, he was open to the incipient mechanistic materialism of his time and that he transmitted its influence, particularly through his ethical and psychological (sensationalist) teaching, to the social sciences. It is relevant to note that though he was not a good, let alone creative, mathematician and physicist, he took a more than dilettantic interest in both these fields; and that all this did not prevent him from making several excursions into speculative theology besides using theological arguments and biblical quotations within his sociological analysis.

---

[1] This term I have adopted on the advice of Professor A. P. Usher.

John Locke, the philosopher (1632-1704; a first and incomplete collection of his works appeared in 1714, a nine-volume one in 1853; there are many lives), was also a product of Oxford. He started his career by tutoring and lecturing and then entered the civil service, in which, under the wings of Whig protectors (whom he furnished with advice and ideologies), he eventually rose to a seat in the Board of Trade. His work is of first rate importance for us on a number of counts. First, as a philosopher in the narrow sense of the word, he led the empiricist tendency to victory first in England and then on the Continent, especially in France, as against Cartesian rationalism (the decisive work was his *Essay concerning Human Understanding*, publ. 1690). This was indeed a break with the scholastic tradition (Aristotle) and a quite decisive one. The reader should reflect, however, that this *does not imply that there was a similar break in political or economic theory:* it is essential to keep these things distinct. Second, as an advocate of (qualified) tolerance, of the liberty of the press, and of extended education, Locke was instrumental in building up the general scheme of later political liberalism, which fact must be mentioned in passing because of its relation to economic liberalism. Third, as a political theorist (see especially his *Two Treatises of Government*, publ. 1690) Locke may claim a front rank place among the philosophers of natural law, though he added little to Grotius and Pufendorf. Fourth, as an economist (see below, ch. 6) he made significant contributions which will, however, be dealt with in another connection because they stand in no relation to either his philosophy or his political theory. Finally, we must again note his theological interests (see especially his *Reasonableness of Christianity*, 1695).

Samuel von Pufendorf (1632-94) was a jurist of the academic type and successively professor at the Universities of Heidelberg, Lund (Sweden), and Berlin. He was not much more than a follower of Grotius. But he wrote a treatise that became a textbook of international reputation and sums up and represents the whole structure of the social science of the philosophers of natural law much better than do the works of the greater men mentioned before: *De jure naturae et gentium, libri octo* (1st ed. [the one used], 1672); more important than his earlier *Elementa jurisprudentiae universalis* (1660). It is the work to consult to get a general idea of the range and level of that type of social science. Moreover, Pufendorf went much further into economics than did Grotius (Book v, chs. 1-8), though he still does not seem to me to have added much to the stock of knowledge and to the analytic apparatus of the late scholastics. But he presented the material in a systematic form. Characteristically enough, he also wrote a theological tract: *De habitu christianae religionis ad vitam civilem.*

Other names might be mentioned, among them some the reader is likely to miss. But the great name of Leibniz and that of his faithful henchman, Christian Wolff, are left out advisedly: they were polyhistors, of course, and greatly interested, among other things, in the economic events and policies of their day; but they made no contribution to our subject. However, perhaps I should have mentioned Thomasius (1655-1728) because his writings shed interesting light on the concept of natural law as used by the group.

Exactly like the scholastics, the philosophers of natural law aimed at a comprehensive social science—a comprehensive theory of society in all its aspects and activities—in which economics was neither a very important nor an independent element. This social science of the philosophers first appeared in the form of systems of jurisprudence that were similar to the scholastic treatises *De justitia et jure:* Grotius and Pufendorf were primarily lawyers and their treatises are primarily treatises on law. They dealt with legal and political principles for which very general validity was claimed on the ground that they were natural in the sense that they derived from general properties of human nature and not, like positive law, from the particular conditions of individual countries.[2] And all the rest of what has been said in the preceding section about the methodological character and the various meanings of natural law of the late scholastics, particularly on the relation between its normative and its analytic aspect, would now have to be repeated for the natural law of the laical philosophers. But though it is grossly inaccurate either to ascribe to the latter the conception itself and its exploitation for purely analytic purposes, or to style them as innovators who rose against scholastic methods of thought, there are several contributions of theirs to record, some of them more felicitous than others.

(b) *Mathematics and Physics.* The philosophers of natural law lived in the heroic age of mathematics and physics. Spectacular discoveries in what for the general public—though not for us—was the 'new experimental philosophy' were attended by no less spectacular popularity of physics, even with mere men of letters and great ladies. First in Italy, then everywhere else, experimenters and mathematicians gathered in order to discuss results and fight out differences; but their meetings drew the curious who wished to have things explained and were welcomed because of the assistance they were able to render financially and otherwise.[3] Those successes and this fashion were not lost upon the philosophers of natural law. They—or some of them—looked at their tools and wondered whether they did not after all bear some similarity to those of the victorious physicists; Pufendorf professed to use a ***methodus mathematica***, though actually he did not do so. Hobbes declared that 'civil philosophy'—a term clearly used for the sake of the parallelism to natural philosophy in the sense of physical science—dated from the publication of his own book, *De cive* (1642), and that he was the first to apply to this civil philosophy the methods of Copernicus and Galileo (which he, however, conceived of as deduction from an abstract and universal 'law of motion'). This sort of thing, mere talk though it was, had a most unfortunate consequence.

---

[2] Hobbes, *Leviathan,* I, chs. 14 and 15, enumerated 19 such principles which he called natural laws. The 'science' of these laws he called Moral Philosophy, a term that will presently be introduced in a different sense.

[3] For our purpose, it will suffice to mention the example of the English Royal Society, chartered, after having existed informally for about twenty years, in 1662—King Charles II took a dilettantic but intelligent interest in it. For a century to come, it was precisely such a gathering of professional physicists and interested laymen. Sir Isaac Newton (1642-1727) was president from 1703 to his death and published his *Philosophiae naturalis principia mathematica* (1687) under its auspices. Its organ, the *Philosophical Transactions,* began to appear shortly after the granting of the charter. The term Natural Philosophy was used to denote what we call the physical (as distinguished from social) sciences until the first decades of the nineteenth century. This use of the word 'natural' further contributed to confusion.

It was, I believe, the curiosity awakened by the achievements of the physical sciences which, spreading beyond its original habitat, created a demand for a type of work that was substantially new, the encyclopaedia. The first achievements in this field were Pierre Bayle's (1647-1706) *Dictionnaire historique et critique* (1697)—the forerunner of the much more comprehensive work of the *encyclopédistes* of the eighteenth century whom we shall mention later on—and John Harris' *Lexicon technicum* (1704).

We have seen that later critics, mainly those in sympathy with the historical school, attacked the natural law concept on the ground that it was metaphysical and speculative. Other nineteenth century writers who took that talk at its face value, as critics are apt to do, condemned it as too 'naturalist,' that is to say, as implying an attempt to copy physical methods of analysis. It even happened that the same critic raised both objections, which, in addition to being unfounded, are mutually exclusive. So the unfortunate concept of natural law eventually met disaster under fire from two opposite quarters. Or rather, the phrase did; for the idea lived on.

It cannot even be asserted that the laical philosophers were less theology-minded than the late scholastics, though theirs was, of course, a different theology. They wrote books on theological questions. They quoted scripture in support of their arguments. The fourth Part of Hobbes's ***Leviathan*** (1651) is entitled 'Of the Kingdom of Darknesse' and contains a chapter on Daemonology, though the demons are no doubt reduced to a symbolic existence as are angels in the third Part.

(c) *Economic and Political Sociology.* Into this conception of human nature the philosophers of natural law introduced elements which, though not entirely new, received an emphasis that was. The more important of these are due to Hobbes. The scholastic doctors had implied that private property owes its origin, in part, to the necessity of avoiding a chaotic struggle for goods, and government its origin to the necessity of enforcing peace and order. But they did not go as far as to speak of an original war of all against all (***bellum omnium contra omnes***) or of every man's being a wolf to every other man (***homo homini lupus***). This sort of thing did not become general doctrine and can hardly be called an analytic improvement. Similarly, the social contract, more delicately adumbrated by the doctors and by Grotius, came out with brutal naïveté in Hobbes's system. In the *Leviathan* (II, chs. 17 and 18) he lets a commonwealth or *civitas*, 'that great Leviathan,' actually be generated by an agreement or covenant, which everyone enters into with everyone else for the purpose of transferring each one's right to govern himself to a man or an assembly of men. This doctrine, restated in its baldest as well as most influential form by Locke, did command almost general assent. But the omnipotence with which Hobbes invested this government did not; Locke in particular was in no mind to argue that the subjects cannot change the form of government, and that the power of the government cannot be forfeited. In any case, the thesis of governmental omnipotence has no analytic standing. For it is not, like some of the juridical arguments of the doctors and the philosophers, the cloak of an analytic proposition, but just a juridical argument and nothing else; Hobbes simply deduced it from the imaginary covenant by arbitrarily interpreting it in such a way as to imply unconditional surrender of the citizen. Finally, we may note that Locke 'justified' private property from everyone's right to his own person, which includes the right to one's labor, which includes the right to the results of one's labor—again a purely juridical argument and an obviously inadequate one at that. It hardly needs to be added that this argument has nothing whatever to do with a labor theory of value.

If this were all, then the contribution of the philosophers to political and economic sociology would be indeed a poor one. But there is something else, namely, a contribution to what we may call Metasociology or Philosophical Anthropology: some of the philosophers probed into that human nature from which their natural laws were to be derived.[4] Again, Hobbes is the outstanding example. The first Part of the *Leviathan*, entitled 'Of Man,' which leads up to the natural-law concept, blocks out a whole philosophy of the human mind and deals with the psychology and social psychology of thought, imagination, speech, religion, and the like. Much of this has Aristotelian and scholastic roots, though Hobbes adopted the all but general practice of indicating antagonism where there was development. But, in a definite direction, he actually went much further than either Aristotle or the scholastics had gone. He defined 'thought'—an individual thought, the same thing as Locke's 'idea'—as the 'representation of an external object' and let the human mind be furnished by sense impression. It may indeed be asserted that he anticipated the substance of Locke's empiricism as well as the principle of associationist psychology that was to become so closely allied to economics in the times of the two Mills, father and son (see below, Part III, ch. 3, sec. 5).

> By Philosophical Empiricism we mean the doctrine, adumbrated by the Greeks (Aristotle, Epicureans, Stoics) but developed mainly by English thinkers of the seventeenth and eighteenth centuries (especially by Hobbes, Locke, and Hume), that (a) all knowledge of the individual is derived through experience during his own life; (b) that this experience may be equated to the sense impressions to which his mind is exposed; (c) that prior to this experience his mind is not only a complete blank but even without 'conative' activity of its own and also without innate ideas in the sense of categories by which the sense impressions are marshalled—so that it would perhaps be logical to say that, as such, 'mind' does not exist at all; (d) that the impressions are the ultimate elements into which all mental phenomena may be resolved, not only remembrance, attention, reasoning—including the construction of causal sequences—but also the affective ones, the 'passions': all these are but

---

[4] Metasociology, then, denotes investigations into human nature or human behavior or, more generally, into the wide realm of all the facts that, though relevant for sociology, do not belong to it in a professional sense but lie beyond or behind it, such as investigations into the formation of habits or into the properties of physical environments. Analogously, we may speak of Metaeconomics. The term Philosophical Anthropology denotes the same thing as Metasociology, the adjective distinguishing it from Anthropology in the usual sense (study of physical characteristics).

agglomerations of elemental impressions and produced by their random 'associations.' This resolution of the human 'mind' or 'soul' into atomic impressions may be likened to the reduction of all physical phenomena to atomistic mechanics, a much employed analogy that made empiricism popular to some and hateful to other people. The reader will please observe that the term Empiricism is here used in what is only one of its many meanings, which is why the adjective Philosophical is added. It has, in particular, *nothing whatever to do* with Scientific Empiricism, a term that merely denotes the attitude that extols the roles of experiment and observation at the expense of that of 'theory.' More specific labels are Sensualism or Sensationalism.

As a philosophy, Empiricism or Sensualism or Sensationalism, although brilliantly defended by Hume in the eighteenth century and by J. S. Mill in the nineteenth, and although it always had a considerable vogue among English nonphilosophers, did not wear well. Leibniz raised the obvious though not decisive objection—what is it?—at the beginning of the eighteenth century. Bishop Berkeley, a little later, produced a different argument that amounted to rejection (*Principles of Human Knowledge*, 1710), and even in England, let alone Scotland or Germany, the battle among professional philosophers went mostly against it. But Associationist Psychology fared much better and in fact commanded the explicit or implicit allegiance of English economists and their continental allies until about 1900 and beyond. A distinguished economist, James Mill, is even responsible for its most uncompromising nineteenth-century exposition. By Psychological Associationism we mean exactly the same doctrine that we called Philosophical Empiricism before. The difference that calls for a separate term is this. Whereas the latter is, or pretends to be, a philosophy in the strict sense of the term and also an epistemology or theory of knowledge, the former denotes the same doctrine, but considered as a fundamental hypothesis in the study of the various problems that come within the professional field of psychology, such as the theory of imagination, or attention, or language, and so on. The reader is requested to keep all this in mind for future reference.

Another point cannot be too strongly impressed upon the reader. The scholastic doctors had taught the doctrines of natural liberty and natural equality of men. With them, however, this natural equality was not an assertion about facts of human nature but a moral ideal or postulate: it rested on Christian beliefs such as that the Saviour died for the salvation of all. But Hobbes, when explaining the conditions that produce his original state of war of all against all, asserted *as a fact* (*Leviathan*, ch. 13) that man's faculties of mind and body are about equal in the sense that the range of their variations is so narrowly limited as *to make complete equality a permissible working hypothesis*. And this was the general opinion of the philosophers. Henceforth we denote this proposition by the phrase Analytic Equalitarianism in order to distinguish it from the Christian ideal, which we shall call Normative

Equalitarianism. Now, first, it should be obvious that analytic equalitarianism is of immense importance, not only for economic sociology and not only for the wider implications of economics proper, but also for many problems of economic theory itself. We need only replace it by the opposite assertion of fact in order to realize that this would change the whole picture of the economic process. Second, with few exceptions and with little qualification, most economists have accepted, and are accepting to this day, analytic equalitarianism. But they never made any serious attempt to verify it, though one would think that they had every reason for making sure of the reliability of such a pillar of their analytic structures. We shall return to this most curious fact in our survey of the *Wealth of Nations*.

(d) *Contribution to Economics*. The economics of the philosophers could have been taken from Molina. It will suffice to advert to the well-rounded presentation in Pufendorf's treatise. Distinguishing value in use and value in exchange (or *pretium eminens*), he lets the latter be determined by the relative scarcity or abundance of goods and money. Market price then gravitates toward the costs that must normally be incurred in production. His analysis of interest (in which he proves himself not averse to biblical quotations) is distinctly inferior to that of the late scholastics. He goes on to discuss various problems of public policy, such as the repression of luxury by sumptuary laws, the regulation of monopolies, craft guilds, inheritance, entails, population. Good sense and moderation are invariably in evidence as is also a sense of the historic flux of things. The welfare aspect is always kept in view. Again, we behold an embryonic *Wealth of Nations*.

7. THE PHILOSOPHERS OF NATURAL LAW: NATURAL-LAW ANALYSIS IN THE EIGHTEENTH CENTURY AND AFTER

By 1700, developments that are to be surveyed in the next chapter had already outdistanced the economics of the philosophers of natural law. It will prove helpful, however, to stay for a moment in order to follow the subsequent fortunes of that little body of economic truth until it loses its individuality and, merging with a broader stream, vanishes from our sight (see below, subsec. g).

The sixty or seventy years that preceded the French Revolution are commonly referred to as the Enlightenment. This phrase is meant to indicate quickened advance on many fronts, or rather a quickened sense of advance—general enthusiasm for progress and reforms. Applying reason to what appeared to be the heap of nonsense inherited from the past was the program of the epoch. A wave of religious, political, and economic criticism that was pathetically uncritical of its own dogmatic standards swept over the intellectual centers of Europe. French society in particular was rapidly disintegrating, but as yet felt perfectly safe. Like all disintegrating societies that do not want to face their danger, it delighted in protecting its enemies and thus provided a milieu of unique charm for a literature that will attract even those of us who sense a flavor of decay—and sometimes, what is worse, also a flavor of mediocrity—

when they turn to these old volumes that harbor so much complacency. The best antidote to the compliments that the men of that self-styled Age of Reason were in the habit of paying to themselves is to read them. Fortunately, there are better performances to record than those of Voltaire and Rousseau. It is, however, impossible to convey, in the space available, a picture of either that intellectual situation or its social background.[1] We can only touch upon the irreducible minimum of essential points.

[(a) *The Science of Human Nature: Psychologism.*] The only fact that need be noticed in matters of theology is that a Natural Theology as distinguished from the *sacra doctrina*—remember that this distinction goes back to the thirteenth century—definitely established itself as a separate field of *laical* social science. Its properly theological contents tended to shrink to an insipid Deism.[2] But more interesting was the development of a sociology of religion—a theory of the origin and social practice of religious ideas—the first substantial beginnings of which we located with Hobbes. The most important fact about philosophical thought is the victorious progress of English empiricism or sensationalism—of Hobbes's and Locke's teaching—which is all the more remarkable because, methodologically, it does not agree as well as does philosophical rationalism with all the claims that were being made, in theology and elsewhere, on behalf of *la raison*. This, of course, greatly favored the success of associationist psychology. Let us call a halt in order to glance at three figures who are not only of outstanding importance for us but also representative of the spirit of the age at its highest, Condillac, Hume, and Hartley. The first two we shall meet again in the role of simple economists. The third points directly to James Mill's performance of 1829.[8] All three did not philosophize simply for the sake of philosophizing but in order to develop the Science of Man or of Human Nature that was to be the basis of the science—or the sciences—of society: more than anything else, they were metasociologists or philosophical anthropologists. No doubt, they were convinced that both in aim and method—the 'experimental' method, for which they invoked the authority of Francis Bacon—their work meant a new departure. All the more important is it to realize that this was not the case. In aim as well as in method they had been clearly anticipated by Hobbes. But we know that Hobbes, though original in a number of important individual points, was a philosopher of natural law like Grotius or Pufendorf and that in fundamental aim and method he did not differ from them. Condillac, Hume, and Hartley were certainly more articulate; with clearer purpose, they developed this science of human nature more fully. The idea of this science itself, however, and the program of deriving from it the basic propositions of the individual social sciences are the idea and the program of the philosophers of natural law and indirectly of the scholastics. The affinity shows in many details: for instance, the germs of associationist psychology are to be found in Aristotle's concepts of similarity and contiguity and in the corresponding concepts of scholastic psychology. Moreover, the methods actually used by the eighteenth-century men were exactly the same as, and in particular not more 'experimental' than, those of their predecessors. Therefore, just as we expressed an important aspect of the work of the philosophers of natural law by calling them laical scholastics, so we may now express an important aspect of the work of the Condillacs, Humes, and Hartleys by calling them eighteenth-century philosophers of natural law.[1] Two points about this science of man are of special interest for us.

---

[1] Both have been described innumerable times. It is very difficult, however, to present a helpful selection. Perhaps the best advice to give is that the reader turn to Hippolyte Taine's famous book, *Les Origines de la France contemporaine* (1876-93) or to Henri Sée's *Les Idées politiques en France au XVIIIe siècle* (1920). But the portrait not only of an individual but of a civilization is so excellently drawn by Lytton Strachey in a brief essay on Morellet (*Portraits in Miniature*, 1931) that half an hour invested in reading it plus another half-hour of pondering over it will do more for the reader than would many hours spent on heavier works. For England, Sir Leslie Stephen's old standard work, *History of English Thought in the Eighteenth Century* (1876), or his *English Literature and Society in the Eighteenth Century* (1904), and H. J. Laski's *Political Thought in England from Locke to Bentham* (1920) may be recommended. J. Bonar's *Philosophy and Political Economy* (3rd ed., 1922) is always a stand-by, of course.

[2] This statement illustrates well the difficulties inherent in the drawing of any sketches such as this. It had to be made in order not to miss an important background fact, and it is of course true. Nevertheless, it is quite misleading in its effects. On the one hand, it misses the affinity of mere Deism with frank philosophical materialism and hence its true nature. Therefore, let us note the fact that philosophical materialism also developed in a form in which it was not known in the Middle Ages. Holbach's *Système de la nature* (1770) may stand as an example. On the other hand, the statement in our text neglects the fact that in the eighteenth century there were a number of religious revivals which are the symptoms of currents that perhaps sum up to more than the Deism and materialism combined. This holds even for France: the intellectual activity within the French Church is, of course, not wholly represented by infidel abbés whose cloth was important to them chiefly as a title to prebends. In this connection, the activities of the Société de l'abbaye de Saint-Germain-des-Prés, of which Jean Mabillon was the center, should be mentioned. We must hurry on, however.

---

[8] Étienne Bonnot de Condillac (1714-80, *Oeuvres complètes*, 1821-2; see, for general information, R. Lenoir's *Condillac*, 1924), worked out Locke's sensationalism into an elaborate system (*Essai sur l'origine des connaissances humaines*, 1746; *Traité des sensations*, 1754), which constitutes the most important continental response to the English lead, both in its philosophical and in its psychological aspects. But the achievement does not consist in systematic elaboration only, for the work presents many original elements, and some of them, such as the theory of the role of language and other symbolisms (*Langue de calculs*, 1798), point far into the future, in spite of the introspective method used, even to the Watsonian behaviorism of our time.

David Hume (1711-76)—who, among other things, exerted formative influence on A. Smith—claims our attention in three quite different and almost unconnected incarnations: as an economist, in which incarnation he swam outside of the natural-law current now under discussion; as a historian, in which incarnation he will be noticed presently; and as a philosopher and metasociologist, which is the incarnation that matters just now. The work of his youth—strikingly illustrative both of the truth of Ostwald's thesis that original creation is the privilege of men under thirty and of the other truth that part of this subjective originality is due to the young author's blissful ignorance of the previous development of his subject—the *Treatise of Human Nature: being an Attempt to introduce the Experimental Method of Reasoning* (sic, J. A. S.) *into Moral Subjects* (1st two vols., 1739, 3rd vol., 1740), remodeled (unfelicitously) into the *Philosophical Essays* of 1748 (republished as *Enquiry concerning Human Understanding*, 1758) is the most important stepping stone between Locke and Kant, far above the former and almost on the intellectual level of the latter. The most important contribution was Hume's theory of causality. This also was Hume's opinion, for it is this topic he singled out for relatively full treatment in the *Abstract of a Treatise of Human Nature* which he published in 1740 and which was retrieved and republished in 1938 with an introduction by J. M. Keynes and P. Sraffa. *Works* (modern ed. by Green and Grose, with introduction and bibliography); *Life and Correspondence* by J. H. Burton (1846); *Letters to Strahan*, ed. by J. Birkbeck Hill (1888). Further *Letters* of great interest, ed. by J. Y. T. Greig (1932).

David Hartley (1705-57) was not, any more than was Condillac, the father of associationist psychology. But his *Observations on Man* . . . (1749) did for it what, to use an economic analogy that the reader will appreciate later, Malthus' *Essay on Population* was to do for the theory contained in it. Also he imparted to it a slant that was new, so far as I know: he linked sense impressions and their associations with 'nerve vibrations' and thus psychology with physiology. Finally, he worked out a theory of ethics and even of natural theology on this basis.

First, the metasociology of Condillac, Hartley, and Hume was essentially psychological. And their associationist psychology was essentially introspective, that is to say, it admitted the analyst's observation of his own psychic processes as a valid source of information. Both these features are of obvious significance for the history of economic analysis but we are now particularly interested in the first. Those authors and most of their contemporaries evidently believed that psychological considerations will explain not only the psychological mechanisms of individual and group behavior, and the ways in which social facts are reflected in, and interpreted by, individual or group minds, but also these social facts themselves. They would not have denied, of course, that in order to explain any actual event, institution, or process we must also take account of facts other than psychological. But they did not develop any general theories about them or admit them into their metasociology: the only stock of general knowledge needed in all the branches of science that have anything to do with human actions or attitudes was psychology and all these branches of science were nothing but applied psychology.

---

[1] The affinity I wished to exhibit may be underlined by a contrast: modern specialists in the various social sciences never think of looking to a mother science of human nature for guidance. They just attack the facts and problems of their special fields directly, using the methods and making the hypotheses that seem most useful for their particular purposes. In fact, if there be any particular 'modernity' about such authors as Hume—apart from their hostility to metaphysics—it would have to be found in the facts that they failed to carry out their program and that, as economists, for instance, they actually reasoned without much reference to their science of human nature. This is one of the reasons why their economics will be dealt with separately.

This view is, however, not the only possible one. We may think that other than psychological data, for instance, geographical, technological, biological facts, are much more important in the practical work of analysis than anything a psychological science of human nature has to contribute. Hence metasociology should be built up from materials other than psychological; and even—which was, for instance, the opinion of Karl Marx—that social processes are governed by a super-individual logic of their own, to the understanding of which the psychology of individuals and groups has nothing to contribute except the knowledge of surface phenomena for the sake of which, moreover, it is not necessary to go very far into psychology. No matter which of these two views of the nature and method of the social sciences we make our own, we must never forget that the one sponsored by our representative authors cannot simply be taken for granted. In order to emphasize this we will give it a distinctive label, Psychologism.

Second, the sociology that was based upon that science of man tended to overstress, just as Aristotle's had overstressed, the element of rationality in behavior. It is therefore interesting to note that the best brains began to react against this. For instance—curious lag phenomenon!—while the *contrat social* was carried to the high-water mark of its popularity by such writers as Rousseau, Hume already denounced it as a completely imaginary and, moreover, unnecessary construct. In addition, he fired another shot at a similar target when he penned the pithy sentence: ''tis not, therefore, reason which is the guide of life but custom' (*Abstract*, p. 16).

[(b) *Analytic Aesthetics and Ethics.*] The way in which that fundamental science of man—of human nature, human knowledge, and human behavior—produced all sorts of 'natural laws' may be illustrated best by what may be described as the English 'natural aesthetics' and the 'natural ethics' of the eighteenth century. Of course, not all speculations on aesthetics and ethics were offshoots of that science, even in England, but we are interested only in those that were, because these present highly revealing analysis by methods that were to serve economic analysis for more than a century to come.

Natural aesthetics and ethics were, first, analytic aesthetics and ethics: though the normative purpose was never discarded, it was not allowed to interfere with the primary task of explaining actual behavior. This analytic point of view had been brought to the fore already during the seventeenth century, for aesthetics, by a number of Italian writers and, for ethics, by Hobbes and Spinoza.[5] Second, the analytic task was tackled in the spirit of what was defined above as psychologism: not only was psychology to provide the approach to the aesthetical and ethical phenomena, but it was to explain all there was to explain about them. Third, the psychology actually used, though not always strictly associationist, was always individual psychology, introspective, and *of the most primitive* kind, rarely if ever involving anything beyond some simple hypothesis about the reactions of the individual psyche from which everything else followed by deduction. Aesthetical and ethical values were thus explained in a manner suggestive of that in which Italian and French economists in the eighteenth century, and the majority of economists of all countries in the nineteenth, explained economic values. This procedure was called empirical and in a sense it was, but only in the sense in which, for example, the Jevons-Menger-Walras theory of marginal utility is. There was nothing 'experimental' or inductive about it and it was in fact not very realistic, notwithstanding all the programmatic utterances, war cries, and appeals to Francis Bacon.

---

[5] Baruch Spinoza (1632-77). The two works relevant to the subject in hand are his *Ethics* and his *Tractatus politicus* (both of which appeared posthumously, 1677). The purely scientific program in question is obscured by the fact that Spinoza's ethics eventually weld into a highly metaphysical system. But he did emphasize the necessity of analyzing human passions as they are instead of preaching about them. Since this is our only opportunity of saluting that great thinker, let me quote here a sentence of his which, though it refers to politics and ethics, every economist ought to be able to repeat on his deathbed: *ut ea quae ad hanc scientiam spectant, eadem animi libertate, qua res mathematicas solemus, inquirerem sedulo curavi* (I have sedulously tried

Aesthetics, then, tended to shrink, so far as this school of thought is concerned, to an analysis of the pleasurable sensations evoked by a work of art, the psychology of the creative effort of the artist receiving less attention.[6] In order to exhibit the analogy that interests us, we shall compare the objective fact that a work of art is considered as 'beautiful' in a given social group with the objective fact of market price. The aesthetic theory in question will then be seen to explain the former fact by subjective valuations of the members of the group, much as the analogous economic theory explains the latter fact by subjective valuations of the individuals participating in a market. In both cases subjective valuation creates the objective value—we know that this had been taught, in the case of commodities, by the scholastic doctors—and not the other way round: a thing is beautiful because it pleases, it does not please because it is 'objectively' beautiful. Of course, we may go on to ask why certain things please certain people and we may probe into the origins of our ideas about the beautiful. But however far we may get in these and similar problems, we always move within the range of a particular conception of the meaning of things, even if we introduce, by special hypothesis, a 'sense' of the beautiful. Different authors went to different lengths in 'subjectivizing' aesthetics. Nevertheless, it was this subjectivization that constituted the main contribution of the school in question and which, moreover, its members felt to be the particularly realistic or 'experimental' or nonspeculative element in it. The principal English authors to mention are Shaftesbury, Hutcheson, Hume, and Alison. The first three are much more important for ethics.[7]

---

to deal with the subject of this science with the same serene detachment to which we are accustomed in mathematics).

[6] This is only broadly true, and even so only for the English theory envisaged. The psycho-sociological meaning of artistic creation was touched upon by Hobbes and subjected to searching analysis by Vico.

[7] A. Ashley Cooper, third Earl of Shaftesbury (1671-1713), the grandson of the politician of doubtful fame. The work that co-ordinates his earlier publications, and hence the only one that needs to be mentioned, is *Characteristicks of Men, Manners,*

The preceding argument fully applies also to ethics but must be supplemented, in this case, by some additional considerations. So far as analytic ethics—analysis of actual conduct—is concerned, the main points of the story are quickly told. Hobbes had described actual conduct, by means of what he supposed to be its determining factor, individual and hedonist egotism. This may have appeared to him as the acme of realism but is, as a matter of fact, nothing but a postulate or hypothesis and an obviously unrealistic one at that. Shaftesbury countered this theory by another hypothesis, the hypothesis of altruism: he explained that for man who habitually lives in society it is just as natural to develop fellow feelings and hence to value the good of other people as it is to develop self-interest and to value his own good. On this he superimposed still another hypothesis, also derived from introspection, according to which the virtuous experience pleasure from doing good irrespective of their appreciation of its effects. This is what is specifically known as Shaftesbury's moral-sense theory, which, though its explanatory value is evidently not great, met with considerable success precisely because of the extreme simplicity of the 'psychology' involved. Shaftesbury's position was systematically elaborated by Hutcheson. And Hume, under the influence of all three, created the moral type of the amiable, easy-going, humane, soberly pleasure-loving egotist that summed up the sort of person he was himself: no asceticism or any other 'monkish' virtue for him—no indeed!—and hence, *of course*, not for anyone else. That unprejudiced analysis of these monkish virtues might, perchance, unearth the true key to the ethical phenomenon was quite beyond his range of vision. Abraham Tucker (1705-74)[8] similarly posited satisfaction of individual desires as the ultimate goal and universal motive of action. I do not think I am wrong in attributing the Hume-Tucker opinion also to Bentham, who held that the only interests an individual can be relied on to consult are his own, but added a qualifying note by emphasizing reasonable or enlightened self-interest that does take account also of other people's interests, feelings, and reactions.

The English moralists of the eighteenth century were, however, no more prepared to do without a normative standard of conduct and judgment than any other moralists ever have been. Some were content to fall back upon a moral law that men know and accept intuitively, an idea that foreshadowed

---

Opinions, Times (1711). Francis Hutcheson (1694-1746), owing to his having been the teacher (and a predecessor in the Glasgow chair) of A. Smith, is for us a 'key man.' A vital and most successful teacher—perhaps all the more successful because he seems not to have despised occasional phraseological fireworks—he exerted widespread influence. His chief work embodies the harvest of years of lecturing: *A System of Moral Philosophy* (publ. posthumously in 1755; see below subsec. c). For the subject in hand, as well as for some subjects that are to follow, we must mention his *Inquiry into the Original of our Ideas of Beauty and Virtue* (1725). See W. R. Scott, *Francis Hutcheson . . .* (1900). Archibald Alison's *Essays on the Nature and Principles of Taste* (1790), is particularly characteristic of the possibilities and limitations of the psychologistic approach.

[8] *Light of Nature Pursued* (1768-77, republ. 1805).

the moral imperative of Kant. Even Locke appealed to such intuition, though this was a bad lapse from grace for an empiricist. But solutions of this type would never have done for Hume or Bentham. To their way of thinking all that was empty metaphysics. At the same time they were quite ready to turn their humane egotism into an ideal, that is to say, to convert their theory of conduct into a source of norms for conduct. We have seen that Hume modeled the moral world to his own image.[9] It is plain that, with delightful naïveté, he thoroughly approved of this image: the schema of his own preferences was the reasonable schema. On the other hand, reason had eliminated all superpersonal values except the good of society. But, in view of that philosophy of human values, what else could this good of society consist in but the sum total of all the satisfactions accruing to all individuals from the realization of their hedonic schemes of preference? If this be so, have we not discovered, at one stroke, the rationale of social values, the relation between them and individual values, and also the only norm of morality that can possibly be meaningful? Affirmative answers to these questions had been suggested already in the seventeenth century, especially by Bishop Cumberland[10] and, less distinctly, by Grotius, who did not go far beyond the common-good concept of the scholastics. The eighteenth-century writers, especially those between Hume and Bentham, only elaborated the fundamental canon of Utilitarian Ethics: good is every action that promotes, bad is every action that impairs, social welfare. Before we consider this canon in its wider aspects, we must glance at a work of particular interest to the economist, that of A. Smith.[11]

With the possible exception of Shaftesbury's this performance must, I think, be placed far above all others. First, he distinguished, like Hutcheson but more clearly than anyone else, between ethics as a theory of behavior and ethics as a theory of people's judgments about behavior, and resolutely concentrated on the latter. Second, this theory of ethical judgment is based upon our ability to place ourselves, as it were, in the other man's place ('sympathy') and to understand him, the judgment of our own acts being then derived from our principles of judging others. Third, the natural is conceived of as that which is psychologically normal—to be analyzed realistically—and not identified with, but distinguished from, the ideal rule of reason (see vol. I, p. 128, 6th ed.). Fourth, the influence of utility upon aesthetic and ethical approbation is not treated simply as a postulate but as a problem in the actual practice of judging (Part IV). Fifth, custom and fashion are not only recognized as relevant factors but systematically investigated (Part V). 'Systems of Moral Philosophy,' that is, theories other than A. Smith's own, come in for criticism that is occasionally trite but on the whole strikingly successful (Part VII). Plan and performance are quite similar to the plan and the performance of the *Wealth of Nations*.

---

[9] This tendency of the social philosopher to exalt his own schema of life's values into an ethical norm from which to judge the habits and tastes of all other men deserves attention because it runs through the whole economic literature and explains a great part of the value judgments of economists. Marshall, for instance, had a very definite conception of the Noble Life (see below, Part IV). It does not take much trouble to realize that this conception was shaped on the model of the typical life of a Cambridge professor. Tastes, pursuits, levels of comfort widely different from it, he at best viewed with indulgence but without ever embracing them with full understanding. It hardly needs to be emphasized how important this is for an appreciation of economists' attitudes to the social worlds they live in.

[10] *De legibus naturae* (1672).

[11] *The Theory of Moral Sentiments*; or, *An Essay towards an Analysis of the Principles by which Men naturally judge concerning the Conduct and Character, first of their Neighbours, and afterwards of themselves. To which is added, A Dissertation on the Origin of Languages.* This is the title of the 6th ed., 1790. The 1st appeared in 1759 under the title of *The Theory of Moral Sentiments.* The differences between the two, though considerable, are (apart from the *Dissertation*) not of any great importance.

[(c) *Self-Interest, the Common Good, and Utilitarianism.*] We know that both Self-Interest and the Common Good were old stagers. But around the middle of the eighteenth century, they asserted themselves with a new energy, not only in ethics, but over the whole field of social thought. In particular, they were, or were supposed to be, the basic and unifying principles of all the social sciences, practically the only ones 'reason' had espoused. Helvétius[12] (1715-71) compared the role of the principle of self-interest in the social world to the role of the law of gravitation in the physical world. Even the great Beccaria[13] went to the length of asserting that man is wholly egotistic and egocentric and does not trouble at all about any other man's (or the common) good. It should be observed once more that this individual self-interest was oriented on rational expectation of individual pleasure and pain,[14] which must, in turn, be defined in a narrowly hedonist sense. It is true that the eighteenth-century authors added qualifications and recognized pleasures that are not usually classed as hedonist, such as pleasures from malevolence, from the acquisition of power, and even from religious belief and practice. In consequence, defenders of that doctrine have been to some extent successful in their attempt to redeem it from the allegation that has made human behavior turn on beefsteaks. But this success—apart from the fact that it does not touch all the other objections that may be raised against any theory that overstresses rationality in behavior—was more apparent than real. For if we go very far beyond the grossest gratifications of the simplest appetites, we come dangerously near to identifying expectation of 'pleasure' with all possible motives whatsoever, even with intentional suffering of pain, and then, of course, the doctrine becomes an empty tautology. Worse still, if we allow too much scope to such 'pleasures' as may be afforded by exertion, victory, cruelty, and the like, we may get a picture of human behavior and of society that differs totally from the one those men actually envisaged. Thus, if we are to derive the conclusion *they* derived from their ideas about pleasure and pain, we have after all no choice but to adopt a definition of the latter that may indeed allow some freedom for going beyond beefsteaks, but only a limited one; that is to say, we have no choice but to adopt a theory of behavior that is at variance with the most obvious facts. Why, then, was it so readily adopted by many good brains? The answer seems to be that these good brains belonged to practical reformers who fought a historically given state of things that seemed to them 'irrational.' In such a struggle, simplicity and even triteness are the chief virtues of an argument, and beefsteak philosophies the best answer to a system of supermundanely sanctified rights and duties. Not that these authors were insincere: we all of us quickly convince ourselves of nonsense that we habitually preach.

---

[12] *De l'Esprit* (1758), Discours II, ch. 2. The book, one of the continental forerunners of English utilitarianism, enjoyed a sweeping success. Few writers have ever professed more naïve and more unconditional belief in education and legislation—that work, of course, upon a perfectly malleable human material which reacts mechanically to physical experience.

[13] The work that is relevant for us at the moment is his famous treatise *Dei delitti e delle pene* (1764), which, a beacon light in the history of the emergence of modern criminal law, illustrates the truth that analytic and practical merit do not necessarily go together.

[14] The standard reference on this subject is Verri's essay on the nature of pleasure and pain published, long after it had circulated and influenced minds, in his *Discorsi di argomento filosofico* (1781). Systematic classification and analysis of the various pleasures and pains is due to Bentham.

We have seen above how the common good or social expediency of the scholastic doctors was harnessed into a particular shape by the eighteenth-century votaries of reason. Let us repeat and reformulate. The pleasures and pains of each individual are assumed to be measurable quantities capable of being (algebraically) added into a quantity called the individual's happiness (*felicità*); a frequently used German term was *Glückseligkeit*. These individual 'happinesses' are again summed up into a social total, *all of them being weighted equally*: 'everyone to count for one, nobody to count for more than one.' Finally, that social total is substituted for, or identified with, the common good or welfare of society, which is thus resolved into individual sensations of pleasure or pain, the only ultimate realities. This yields the normative principle of Utilitarianism, namely, the Greatest Happiness of the Greatest Number, which is chiefly associated, in recognition of ardent advocacy, careful elaboration, and extensive application, with the name of Bentham.[15] If the

---

[15] Jeremy Bentham (1748-1832), trained as a lawyer, though he early retired to a life of research and propaganda, became the undisputed leader of the utilitarian circle and the central figure of a group usually described as Philosophical Radicals. His performance in the field of economics will be noticed elsewhere. Here he interests us as a philosopher, sociologist, and theorist of legislation. The only one of his many voluminous works (ed. John Bowring, 1838-43) that need be mentioned is *An Introduction to the Principles of Morals and Legislation* (1789), which widely influenced thought and legislative practice though, on the Continent, similar ideas spread from domestic roots particularly in Italy and France.

The essentials of the utilitarian system had, however, been presented before in the *Principles of Moral and Political Philosophy* (1785) by William Paley (1743-1805), and some of them in the *Essay on the first Principles of Government* (1768) by Joseph Priestley (1733-1804), the versatile theologian and scientist who, besides being idea was of ancient origin and grew so slowly as to defy dating, the slogan itself may be dated more precisely: so far as I know, it occurs first in Hutcheson (op. cit. 1725), then in Beccaria (op. cit. 1764, *la massima felicità divisa nel maggior numero*); after that in Priestley (op. cit. 1768), to whom Bentham gives the credit for what to him was a 'sacred truth.' Hume does not have the slogan, but should be included in this series all the same. The word Utilitarianism is Bentham's.[16]

The essential point to grasp is that utilitarianism was nothing but another natural-law system. This holds not only in the sense that the utilitarians were the historical successors of the seventeenth-century philosophers of natural law; nor only in the sense that the utilitarian system developed from the system of the philosophers which, though evident, can be proved in detail from the history of ethics, on the one hand, and from the history of the common-good concept, on the other; but it holds also in the much more significant sense, that in approach, in methodology, and in the nature of its results utilitarianism actually was another, the last, natural-law system. The program of deriving, by the light of reason, 'laws' about man in society from a very stable and highly simplified human nature fits the utilitarians not less well than the philosophers or the scholastics; and if we look at this human nature and the way in which it was supposed to work, as we did above, we realize that the affinity goes much further than that.

> Like the systems of the philosophers or the scholastics, utilitarianism presents a threefold appeal. First it was a philosophy of life, exhibiting a scheme of 'ultimate values.' It is here that we must look for the source of the ineradicable impression that utilitarianism, Bentham's especially, was something new and fundamentally antagonistic to the older systems. But, as the reader should know by now, the difference was not great so far as the philosophy of the current business of everyday life is concerned.

---

a church historian of note and a famous controversialist on theological matters, was also a recognized research worker in electricity and chemistry. That essay may be called the bridge between Locke's theory of government and James Mill's unfortunate exploits in this field. Neither Paley nor Priestley, however, contributed much that cannot be found in earlier writings, e.g. in Cumberland's work already referred to. Of continental 'precursors' it is sufficient to mention again Beccaria, Verri, and Helvétius. With Beccaria, the relation, to be presently discussed, of utilitarianism to earlier natural-law systems is particularly clear.

From the large literature on English utilitarianism and on the Philosophical Radicals, J. S. Mill's essay on *Utilitarianism* (publ. 1863) deserves the reader's first attention. Also see: Sir Leslie Stephen's work, *The English Utilitarians* (1900), H. J. Laski's *Political Thought* . . . already referred to, W. L. Davidson's *Political Thought in England: The Utilitarians from Bentham to J. S. Mill* (1915), and Graham Wallas' charming book on *Francis Place* (1898).

[16] The interesting note of skepticism sounded by A. Smith in a famous dictum of his should be recorded here: he remarked in passing that, so far as conscious happiness is concerned, there is not much difference between any state that we accept as permanent and any other.

For the sphere of stable, barn, shop, and market, the scholastic doctors were utilitarian enough. The real difference was that the doctors confined the utilitarian point of view to purely utilitarian activity where it is (nearly—not even there wholly) adequate, whereas the utilitarians reduced the whole world of human values to the same schema, ruling out, as contrary to reason, all that really matters to man. Thus they are indeed entitled to the credit of having created something that was new in literature—for it cannot be attributed to Epicurus—namely, the shallowest of all conceivable philosophies of life that stands indeed in a position of irreconcilable antagonism to the rest of them.

Second, utilitarianism was a normative system with a strong legal slant. It was, like the scholastic system, a system of moral imperatives, on the one hand, and of legislative principles, on the other. Bentham considered himself primarily a moralist and legislator,[17] and it was as a criterion of 'good' and 'bad' legislation that the principle of greatest happiness of the greatest number acquired for him paramount importance. Observe once more the equalitarian element in it which was as essential as the element of happiness. And these two together with the belief not only that any individual was very much like any other, but also that every individual was nondescript and malleable material with few or no innate characteristics of his own, then produced the fundamental political 'plank' of Benthamism: educate people and let them vote freely and everything else will take care of itself.[18]

But, third, again like the natural law of the philosophers and the scholastics, utilitarianism also was a comprehensive system of social science embodying a uniform method of analysis. And this aspect of it is separable from the two others in the same sense in which the analytic work of the scholastics and the philosophers is separable from the rest of their thought. In other words, it is logically possible to despise utilitarianism, root and branch, both as a philosophy of life and as a political program and yet to accept it, as an engine of analysis, in all or some of the departments of the social sciences. But since, on the one hand, utilitarianism may be not much more valuable as an engine of analysis than it is in the other two respects and since, on the other hand, many economists have not hesitated to declare that it is basic to economic theory—Jevons even defined economic theory as 'a calculus of pleasure and pain'—the extent of its influence upon analytic work should be cleared up at once.

---

[17] Before Bentham, the catalogue of utilitarian moralists does not quite coincide with the catalogue of utilitarian legislators, and in a more complete exposition it might be advisable to distinguish the histories of moral and political utilitarianism. Most of the important names, however, would occur in both, and in view of the close relation we need not insist further on that distinction.

[18] It should be observed that these political principles do not uniquely determine a man's allegiance to a political party or the position he will take on any practical political question. Bentham impressed his personal preferences upon a group of personal adherents—the Philosophical Radicals already mentioned—and the strong coherence of this group accounts for a definite program (in substance laissez faire combined with universal suffrage) and the impression that this program followed inexorably from analytic premisses. But in other times and countries, the Benthamites might have been conservatives—Hume was, and most of the Italian utilitarians were—or else socialists. There is nothing surprising in this so soon as it is realized that preference plays so large a part in arriving at conclusions as to practical policy that it bends almost any analytic structure to its dictate. A man may accept Marx's analytic work entirely and yet be a conservative in practice.

It is the common failing of laymen, philosophers, and historians of thought to pay exaggerated respect to whatever presents itself as a fundamental principle. Actually, people do not always make use, in scientific work any more than in the practical concerns of life, of the fundamental principles to which they profess allegiance. Utilitarianism being a set of such fundamental principles, we must therefore inquire in every case what role it was allowed to play. So far as economics is concerned, we may, however, return broad answers for four types of cases. First, utilitarian hypotheses are completely valueless in questions of interpretations of history or in questions touching the moving forces of economic history. Second, utilitarian hypotheses are worse than valueless in all problems involving questions of actual schemes of motivation, for example, in such a problem as the economic effects of inheritance. Third, utilitarian hypotheses are in fact basic to that part of economic theory that is usually referred to as Welfare Economics—the heir to Italian eighteenth-century theories on *felicità pubblica*. We adopt these hypotheses habitually when discussing such problems as the effects of 'transfers of wealth from the relatively rich to the relatively poor.' And this is precisely the reason why the propositions of welfare economics never convince anyone who is not already convinced beforehand and irrespective of any argument. For though there is, of course, an aspect of these problems to which the utilitarian approach is appropriate—provided we believe it to be methodologically admissible—this aspect is evidently not the only one: we have proved very little, when we have proved that transferring a rich man's dollar to a poor man increases welfare in the utilitarian sense. Fourth, in the field of economic theory in the narrowest sense of the term, utilitarian hypotheses are unnecessary but harmless. For instance, we can state and discuss the properties of economic equilibrium without introducing them. But if we do introduce them, results are not materially affected, hence not impaired. This makes it possible for us to salvage much of economic analysis that at first sight seems hopelessly vitiated by utilitarian preconceptions.

[(d) *Historical Sociology*.] The writers of the eighteenth century have often been blamed for lack of 'historical sense,' a disability that went in fact so far with some of them as to make them blind to the values of bygone civilizations. All the more necessary is it to point out that the antidote developed along with the disease. If we find, in some instances, the most foolish contempt for

Greek art—Voltaire being put above Homer, for instance—we also find the origins of its modern cult. If we sometimes find a perfectly stupendous absence of interest in history, we also find a rich crop of serious historical work that laid the foundations of nineteenth-century developments. We cannot do more than list five essential points: a good beginning was made with systematic collection of materials; new methods of interpretation and criticism of documents were worked out; [19] economic and cultural history began to divert some of the attention previously all but monopolized by political and military history; the (relatively speaking) detached report that renders documentary evidence began to prevail over epics or preachings (Hume, William Robertson, Gibbon); [20] and the awakening of interest of the public is attested by the success of popular universal and national histories. Of course, there is such a thing as unhistorical history, that is to say, a man may do historical work without ever getting the specifically historical angle. But Hume's *History of England* (8 vols., 1763) was not of this kind. Though hopelessly out of date by now, it will always be a landmark of historiography—which shows that he, at least, was not a slave to his utilitarianism.

Still more noteworthy from our standpoint is the emergence of Historical Sociology—sometimes called Philosophy of History [21]—that is to say, of sociological theories that, on the one hand, used historical material in order to arrive at generalizations and were, on the other hand, intended to explain individual historical states and processes. The greater part of this kind of work was dilettantic and of a nature to disgust serious historians. Some of it was, moreover, unhistorical in the sense just defined: historical fact was often twisted to fit the preconceptions of *la raison*. Nevertheless, there were also considerable and even path-breaking performances. By way of example, I may mention Condorcet, Montesquieu, and one who was one of the greatest thinkers to be found in any age in the field of the social sciences—Vico.[22] Condorcet's

---

[19] F. A. Wolf's (1759-1824) seminal *Prolegomena ad Homerum* appeared in 1795, but was the result of earlier work.

[20] To this day historians have not ceased to preach, to bestow praise and blame, and to air their personal, social, and national prides and hates. What I mean to convey is that substantial progress was made toward presentation of facts in something like a scientific spirit and away from the epic.

[21] See Robert Flint, *History of the Philosophy of History* (1893).

[22] The Marquis de Condorcet (1743-94; *Oeuvres*, ed. 1847-9; English readers are perhaps best referred to Lord Morley's essay on him, republ. in *Critical Miscellanies*, 1886 1908, vol. II), one of the *encyclopédistes* (see below, sub e), roamed over almost all fields of science and policy. Among other things, he was a trained mathematician; his ventures in the application of the calculus of probabilities to legal and political judgments, though not wholly felicitous, gave an important impulse; he propagated 'natural rights,' popular sovereignty, and equal rights for women, and was a great hater of Christianity—in all of which, ardor completely extinguished his critical faculty. His contributions to economics are not worth mentioning. The work relevant here is *Esquisse d'un tableau historique des progrès de l'esprit humain* (1795; English trans. 1802).

Montesquieu (1689-1755) presumably needs no introduction beyond the remark that

Esquisse presents a definite theory of historical evolution or 'progress': its goal is equality[23] and its motive force is the ever-increasing knowledge that the indefinitely perfectible human mind keeps on acquiring. This, of course, is very poor sociology. But the work is the outstanding example of an uncompromisingly 'intellectualist' view of the historical process. In sharp contrast, Montesquieu's *Esprit des lois*, despite inadequate workmanship—especially inadequate as to critical use of material—is serious sociology. The chief virtue of the latter work, both as regards method and performance, is that it envisaged historical states of societies and their changes in the light of a number of objective factors,[24] which yield realistic explanations and in this sense analytic theories but no simple, in particular no rationalist, general formula. This was indeed a new departure and methodologically spelled a significant break with natural-law ideas: it was sociology based upon actual observation of individual temporal and local patterns, not merely of general properties of human nature. For our purposes, this was Montesquieu's essential achievement, foreshadowed in this treatment of the particular case of ancient Rome. His success, at the time and later, was of course due to the appeal of his 'constitutional' theories—*contrebalance des pouvoirs* and the like—which are of no interest to us.

---

he was one of the most influential thinkers of all times and that in particular, though his economics is insignificant—without originality, force, or scholarship—he greatly influenced A. Smith in other respects. The three works to mention are the—also insignificant—*Lettres persanes* (1721), the *Considérations sur les causes de la grandeur des Romains et de leur décadence* (1734), and of course his magnum opus, *De l'Esprit des lois* (1748), which is so much more than mere '*esprit sur les lois*.'

Giambattista Vico (1668-1744; *Opere*, newest ed. Nicolini, 1911-31; bibliography by B. Croce, 1904; revised, enlarged ed. 1947-8). Part of the extensive Vico literature is impaired by attempts of authors to claim the great name for tendencies of their own, but see Croce's essay (English trans. by Collingwood, 1913), R. Flint's *Vico* (1884), and a few beautiful pages on Vico in Tagliacozzo's *Economisti napoletani* (1937); there are several good German books, especially those by Werner and Klemm. Vico was professor in Naples, professing to teach 'all the knowable' (*tutto lo scibile*). The fact that, among other things, he was a lawyer and always stressed legal aspects (the history of law was to him the history of the human mind) is important because it brings out his relation to the philosophers of natural law. The influences that contributed to shaping his thought and the problems raised by the various cases of earlier occurrence of ideas similar to his own are much too complex for us. The Greeks, the Roman jurists, Grotius, the English empiricists, Descartes (by way of antagonism), the scholastics, and many other groups would have to be mentioned, among them also the Arab historian Abu Said Ibn Khaldun (1332-1406; see de Slane's French trans. of the first introductory part of his history, 1863-8, all I know). The only work of Vico's that need be mentioned specifically is *Principii di una scienza nuova* . . . (1725; almost rewritten for the 2nd ed. of 1730).

[23] The sociologist of thought will, of course, see in this a secularized scheme of salvation.

[24] The emphasis upon the influence of geographic environments that may have hailed from Thucydides and may have inspired later anthropogeographical researches such as that of Vidal de la Blache deserves to be specially noticed.

Vico's achievement was quite different and met with little success until late in the nineteenth century. His New Science (*scienza nuova*) is best described by the phrase 'an evolutionary science of mind and society.' But this must not be interpreted to mean that the evolution of the human mind shapes the evolution of human society; nor, though this would be nearer the truth, that the historical evolution of societies shapes the evolution of the human mind; but that mind and society are two aspects of the same evolutionary process. Reason, in the sense of the rational or logical operations of the human mind, is no causal factor in this process which Vico conceived in a thoroughly anti-intellectual spirit. Neither has reason, in the sense of goals or meanings perceived by the observer's reason, anything to do with it: Vico's theory of recurrent processes (*corsi e ricorsi*) emphatically denies any tendency toward, and in fact the existence of, any such goals and meanings. In this scheme philosophy and sociology had become one—thought and action had become one—and this unit was essentially historical in nature.[25] And, after all, though the common currents of eighteenth-century waters did not reach up to his knees, Vico too was eighteenth century.

[(c) *The Encyclopédistes.*] We have had occasion to notice the increase in the demand for dictionaries or encyclopaedias during the seventeenth century. Further increasing during the eighteenth, this demand was satisfied by ever more ambitious ventures (Chambers' *Cyclopaedia*, Zedler's *Universal-Lexicon*, and others). All of these were surpassed by the great French *Encyclopédie* (from 1751 on),[26] which, among other things, excelled the other works of its type and time by the number and quality of its articles on economic subjects. But it is mentioned here for an entirely different reason: whoever believes at all in the concept of the 'spirit' of an age will be inclined to look upon the *Encyclopédie* as the very incarnation of the eighteenth-century spirit. So far as this is correct, the work itself is an important part of the cultural background of which we are trying to reconstruct some patches. But how far is it correct? Like all encyclopaedias of such range, this one contained articles that differed widely not only in quality but also in point of view. The economic articles referred to, for instance, were written by writers as far apart from one another as were Quesnay and Forbonnais, while the bulk of the articles—physics and technology were particularly attended to—left no scope for difference of point of view in the philosophical or political sense. Nevertheless, the strong personality of the editor-in-chief, Diderot, succeeded in imparting some uniformity to what was called the Tower of Babel by hostile critics. In order to realize this, it is sufficient to name a few of the leading members of the circle that gathered round Diderot: d'Alembert, Voltaire, Condorcet, Holbach, Helvétius—all vowed to the service of *la raison* in the particular sense in which it meant enmity to the Christian faith and especially to the Catholic Church. With varying measures of reserve, the opportunity afforded by the articles on history, philosophy, and religion was exploited for purposes of propaganda in that respect. But this was all. In other respects not much uniformity was either aimed at or achieved. The philosophy is mainly empiricist, but not wholly so. The politics reflects the opinions about state, public administration, and policy that were carried far beyond the specifically encyclopaedist circle. Beyond this there was no definite program. In particular, there was no revolutionary program: those intellectuals no doubt had their dig at the regime of Louis XV and occasionally aimed at its special features; on the whole, however, they felt too comfortable to long for a violent upheaval; some of them saw points in the enlightened despots of their time who reformed—and paid well; those who lived to witness the realities of revolution were not very happy about it. Thus, though it remains true that the great French venture may be taken as a symbol of an important current of thought, its importance for us is not as considerable as it seemed to its contemporary enemies, who insured its success by fighting it.

---

[25] This scheme, very obviously, points forward toward Hegel and, less obviously, toward Husserl. This fact explains both his comparative failure in his own day and his success after nearly two centuries. But it should not be allowed to obliterate the purely analytic aspects of his work which parallel (i.e. anticipate) some feature of the less spacious and profound work of Montesquieu, especially as regards emphasis upon environmental factors.

[26] The reader will find more than enough information in the *Encyclopædia Britannica's* article 'Encyclopædia.'

There is one point, however, that should be emphasized or emphasized again (see above, sec. 5), namely, the relation of the thought of the *encyclopédistes* to that of the seventeenth-century philosophers of natural law. The teaching of the latter fared quite well at the hands of the former. The *encyclopédistes*—and all the writers whom this term, in a wider sense, may be said to cover—did not always give credit to the philosophers as they should have done. But they displayed no hostility to the natural-law system and in fact developed its ideas. Nor is this surprising. Was not natural law derived, by reason, from human nature and hence the very embodiment of their own program? And the Natural Rights of the philosophers were, of course, thoroughly to their taste. The religious barrier hid from them the true origin of these ideas: they could not have quoted St. Thomas' statement that the natural law was *rationis regula*. But no such barrier existed in the case of the philosophers who were, at least, no Catholics. And so the *encyclopédistes*, within and without the volumes of the encyclopaedia, and many other men, such as Quesnay, who were not *encyclopédistes* in the strict sense (even if they were contributors), continued to use the philosophers' analytic schema and, sometimes, even their most dubious arguments. Quesnay's *ordre naturel* would be recognizable as an offshoot of the natural-law stem, even if Quesnay had never written his article on *droit naturel*. The Abbé Morellet, an ardent free trader, was quite content to argue that, since man is naturally free and since this implies that he can buy and sell where he pleases, protection stands condemned for violation of natural law—which argument occurs also in other writings of the time and must evidently have impressed some people,[27] a most interesting comment upon the age of reason.

---

[27] The Abbé André Morellet (1727-1819) was, it is true, a very minor light among the *encyclopédistes*—not more than an effective pamphleteer. We need not mention his economic works. But he is interesting as a type, which is why perusal of Lytton Strachey's essay on him has been recommended above. However, he collected materials that went into Peuchet's *Dictionnaire universel de la géographie commerçante* (1799-1800), which is an important link in the long chain of economic or semi-economic dictionaries.

[(f) *The Semi-Socialist Writers.*] It has been stated that, as a body, the *encyclopédistes* were not politically revolutionary. Neither were they socialists. The equalitarianism of the time—both normative and analytic—suggested the criticisms of inequalities, especially great inequalities, of wealth that we find in Helvétius and many other writers. And the obvious weaknesses of natural-law philosophies about the natural right to property that were expounded either on the lines of Locke or in the special form adopted by the physiocrats (see below, ch. 4), invited criticism that sometimes went from attack upon particular arguments in defense of property to attack upon property itself. But though the historian of socialist ideas is no doubt able to compile a lengthy list of socialist or communist or near-communist publications that were not without influence on nineteenth-century socialism, the historian of economic analysis has little of interest to record: he can only agree with Karl Marx's opinion about that literature. It should be observed, however, that socialist or semi-socialist writers, when arguing against conclusions drawn from natural-law premisses by natural-law methods, almost invariably used these premisses and methods themselves. Thus, exactly as the votaries of *la raison* fought scholasticism while remaining its pupils so far as methods and results of analysis are concerned, so the socialist or semi-socialist writers of the eighteenth century remained natural-law philosophers in their way of thinking: the concepts of natural law and of natural rights were quite capable of serving opposite practical aims, and few if any writers thought of attacking the method they embodied. Rousseau, Brissot, Morelly, and Mably are illustrative examples. For the sake of convenience, we add here a very different figure, Godwin, whose only contribution to economic analysis will, however, have to be considered later.

J. J. Rousseau (1712-78), in spite of his glorification of the natural state of society and of equality, can hardly be called a socialist—he was typically what our term 'semi-socialist' is meant to convey. But neither can he be called an economist. His article on political economy in the *Encyclopédie* contains next to no economics. His essay on the origin of inequality (1755) is not a serious effort to account for the phenomenon. In particular, despite some superficial similarities in phrasing, he was not a physiocrat or a forerunner of the physiocrats. Such ideas as he entertained on economic subjects were, however, of considerable influence with the public. J. P. Brissot de Warville (1754-93), a Girondist politician executed in 1793, holds a place among reformers of criminal law. The work relevant for our subject, the *Recherches philosophiques sur le droit de propriété et sur le vol . . .* (1780), is pure natural-law speculation of the kind that made later critics of natural-law sociology and economics completely overlook its serious achievements. The nonexistence of the right to private property is the *thema probandum*. Brissot seems to have been unaware of practically all the realistic and really damaging arguments that may be forged against it. The doctrine that Property is Theft, made famous in the nineteenth century by Proudhon is the centerpiece of the book. Morelly's *Code de la nature* (1755) is a program of full-fledged state communism of considerable merit: it presents, in minute detail, solutions of the practical problems of the structure and management of a communist society, many of which turn up, mostly without acknowledgment, in the nineteenth-century literature of socialism and most of which reflect a sober sense of 'workability.' The doctrine, much more often implied than frankly stated, that all the deviations from normal behavior that are felt to be immoral are caused by the conditions of life in capitalist society, was, so far as I know, first stated in this book. We cannot go beyond pointing out that this book, too, is pure natural-law philosophy: strictly state-controlled communism is the form of existence that corresponds ideally to natural laws discerned by reason. Gabriel Bonnot de Mably (1709-85), though he was not a communist from the beginning, and though in the end he resigned himself to practical programs that did not go beyond rather commonplace reforms, must also be classed as a straight communist on the strength of the implications of the only work that can be mentioned here, *Doutes proposés aux philosophes économistes sur l'ordre naturel et essentiel des sociétés politiques* (1768). This work contains an elaborate attack not only upon the physiocrat theory of private property but also upon private property itself, which is held to be an almost unmixed evil. But though one-sided and otherwise defective analysis, Mably's argument is still analysis of facts and not merely a discussion of 'rights.' The theory that property in land is the ultimate cause of all inequalities of wealth—repeatedly espoused in the nineteenth century and, by F. Oppenheimer in the twentieth—may be wrong, but is still an analytic proposition or theory. The authors mentioned as well as many others have received considerable attention from historians of thought, including economists primarily interested in the history of thought. See, for example, A. Lichtenberger, *Le Socialisme au XVIIIᵉ siècle* (1895).

The French ideas of the Enlightenment were good sailors (crossing the Channel easily), the more so because they had important English—especially empiricist and associationist—roots. High above the common run of enthusiasm rose the book that is to represent this literature for us, William Godwin's *Enquiry concerning Political Justice* (1793). It is only semi-socialist and even this only by virtue of its dogma that property in the product of other people's labor is 'unjust.' Perhaps those are right who, on the strength of Godwin's extreme distaste for violence and compulsion of any kind, class him as an anarchist. In any case, the view of human nature, according to which man's mind is a blank—but indefinitely perfectible—to be filled in by experience conditioned by social institutions has hardly ever, before or after, been made to serve absolute equalitarianism so uncompromisingly. Godwin was indeed goaded into doing a piece of analytic work by the attack of Malthus. But his work itself is essentially nonanalytic and therefore beyond the range of scientific criticism. It expounds a creed that is impervious to argument and at the present time counts more adherents than it ever did.

[(g) *Moral Philosophy*.] All the facts presented above about eighteenth-century thought go to show that the natural-law approach to sociology and economics held its own to a considerable extent and that the notion that a new 'experimental' spirit rose victoriously against it—or else that the cult of *la raison* was something fundamentally new—is as illusory as is the analogous notion that the work of the seventeenth-century philosophers of natural law spelled a violent break with scholastic analysis. In other words, these facts teach a lesson of continuity in development. Nevertheless, the natural-law system of thought disintegrated or, at least, underwent a transformation. We know that, originally, it had been a system of jurisprudence and that all nonlegal material had been fitted into the legal framework in an ancillary role. But in the eighteenth century, the increase of this material and the addition of new fields of research burst that framework. From having been in the position of a governing holding company that unified and co-ordinated everything, 'natural jurisprudence' became merely a specialty of a new comprehensive unit that was no longer primarily legal in character.[28] This new unit was called, especially in Germany and Scotland, Moral Philosophy—the word philosophy being taken in its old sense of the sum total of sciences (St. Thomas' *philosophicae disciplinae*), so that, roughly, moral philosophy means the social sciences (the sciences of 'mind and society') in contrast to Natural Philosophy that denoted the physical sciences plus mathematics. It was the subject of a standard course offered within the university curricula and consisted, mainly, of natural theology, natural ethics, natural jurisprudence, and policy (or 'police') which included economics and also public finance ('revenue').[29] Francis Hutcheson, the teacher of A. Smith, was professor of moral philosophy in this sense at the University of Glasgow, and so was A. Smith. Both the *Moral Sentiments* and the *Wealth of Nations* are blocks cut out from a larger systematic whole. Thus the old universal social science of the scholastic doctors and of the philosophers of natural law survived in the new form. But not for very long. Though the moral-philosophy course figures in university curricula even in the first half of the nineteenth century—universities are conservative—it was rapidly losing, in most places, its old meaning and position toward the end of the eighteenth.

---

[28] As we already know, the Historical School of Jurisprudence was very hostile to this natural jurisprudence and saw nothing in it but entirely unscientific speculation. This view was very influential: it was in fact from the lawyers of this school that people learned to despise everything that was in any way connected with the concept of natural law. It should be repeated, however, that this view, while quite understandable considering the abuse of the idea of natural rights of all kinds, neglects an important nonspeculative core of natural-law analysis. The natural jurisprudence of which I speak in the text was an inadequate but still scientific theory—or general logic—of law for which it is possible to make out a case similar to that which can be made out for economic theory.

[29] The contents of the course varied, however. Also, the division of all sciences into moral and natural philosophy was neither complete nor invariable. Pure philosophy in the narrow sense stood outside and so did logic, philology and literature, history, and other fields.

This was due to the same cause that burst the natural-law system. The accession of material in the individual branches of moral philosophy tended to bring them into the hands of specialists, every one of whom had inevitably to concentrate on his own branch and to neglect both the other branches and the comprehensive principles. This applies with particular force to economics because in this case the new material came from outside (see next chapter). It is highly significant that A. Smith found it impossible to do what Hutcheson had done as a matter of course, namely, to produce a complete system of moral philosophy or social science at one throw. The time for doing this had passed: absorption of the new material—both facts and analyses—had become a full-time job.

As long as this absorption was not consummated, the little body of scientific economic knowledge that had been inherited from the scholastics and nursed along by the philosophers of natural law retained not only independent existence but also a distinctive character of its own. Owing to the greater intellectual refinement of the men who had created it, and to their detachment from the immediately practical issues of economic policy, their economic analysis was different from the analysis of other people. Beholding it we cannot fail to notice more correct formulation of fundamentals and a wider view of practical problems, both anticipating much later opinions. But so soon as that absorption was consummated, we naturally lose sight of it, though we do not lose its contribution. This happened, roughly speaking, between 1776 and 1848: the latest natural-law system, utilitarianism, getting under sail when the economic specialists had established their claim to autonomy, was not, as were its predecessors, able to exert effective control over them.

CHAPTER 3

The Consultant Administrators and the Pamphleteers

1. MORE FACTS FROM SOCIAL HISTORY

WE KNOW ALREADY that, as the eighteenth century wore on, economics settled down into what we have decided to call a Classical Situation, and that, mainly in consequence of this, it then acquired the status of a recognized field of tooled knowledge. But the sifting and co-ordinating works of that period, among which the *Wealth of Nations* was the outstanding success, did not simply broaden and deepen the rivulet that flowed from the studies of the schoolmen and of the philosophers of natural law. They also absorbed the waters of another and more boisterous stream that sprang from the forum where men of affairs, pamphleteers, and, later on, teachers debated the policies of their day. In this chapter we shall take a bird's eye view of the various types of economic literature produced by these debates, reserving for subsequent chapters fuller treatment of works and topics that seem to require it.

This literature is not a logical or historical unit. The men who wrote it, unlike the philosophers of natural law, form no homogeneous group. Nevertheless there is a link between them all which it is necessary to emphasize: they discussed immediately practical problems of economic policy, and these problems were the problems of the rising National State. Therefore, if we are to understand the spirit that animates those writers, their lines of reasoning, the data they took for granted, we must for a moment digress into the sociology of those states whose structure, behavior, and vicissitudes shaped European history—thought as well as action—from the fifteenth century on. The important point to grasp is that neither the emergence nor the behavior ('policies') of those states were simply manifestations of capitalist evolution. Whether we like it or not, we have to face the fact that they were the products of a combination of circumstances that, viewed from the standpoint of the capitalist process as such, must be considered as accidental.[1]

[(a) *Incidental Factors in the Emergence of the National States.*] First, it was an accident that the rise of capitalism impinged upon a social framework of quite unusual strength. 'Feudalism' no doubt gave way, but the warrior classes that had ruled the feudal organism did not. On the contrary, they continued to rule for centuries and the rising bourgeoisie had to submit. They even succeeded in absorbing a great part of the new wealth for their own purposes. The result was a political structure that fostered but also exploited the bourgeois interest and was not bourgeois in nature and spirit: it was feudalism run on a capitalist basis; an aristocratic and military society that fed on capitalism; an amphibial case very far removed from bourgeois control. This pattern produced problems and—'militarist'—angles from which to look at them, which were completely different from what the mere logic of the basic process would lead us to expect.[2] Thus, for the majority of economists, monarchs that were primarily warlords and the class of aristocratic landowners, remained the pivots of the social system as late as the middle of the eighteenth century, at least on the continent of Europe. The reader should therefore apply the requisite qualification to what he has read in the preceding chapter on the increasing social weight of the bourgeoisie.

Also, it was an accident that the conquest of South America produced a torrent of precious metals. The growth of capitalist enterprise might presumably have been expected to produce inflationary situations in any case, but this torrent made a lot of difference to the course of events. In a way that is too obvious to need elaboration, it speeded up capitalist development, but much more important are two other facts about it that point in the opposite direction. On the one hand, this access of liquid means greatly strengthened the position of those rulers who were able to get hold of them. Under the circumstances of the times, this conferred a decisive advantage in the planning of military ventures on lines that often, as for instance in the case of the Spanish Hapsburgs, were quite unconnected with bourgeois interests in the component parts of their farflung empire or with the logic of the capitalist process. On the other hand, the price revolution that ensued [3] spelled social disorganization, and hence was not only a propelling but also a distorting factor. Much that might have been gradual change, if nothing but the basic process had been at work, became explosive in the feverish atmosphere of inflation. Particular notice must be taken of the effect on the agrarian world. By the time that inflation set in, the greater part of the dues that continental peasants owed to their lords had been converted into terms of money. With the purchasing power of money rapidly falling, the lords attempted in many countries to raise the monetary values of those dues. The peasants resisted. Agrarian revolutions were the consequence, and the revolutionary temper thus engendered was an important factor in the political and religious upheavals of that epoch. But, owing to the strength of the top feudal stratum, these revolutions did not, as we might have expected, accelerate social developments in accordance with the basic process. The risings of the peasants and of the other groups that had revolted in sympathy were put down with ruthless energy. The religious movements met with success only so far as they were sponsored by the aristocracies and in the most important cases quickly lost such social or political radicalism as had been originally associated with some of them. Princes and barons, armies and clergies, emerged from the trial with enhanced prestige and power whereas the prestige and the political power of the bourgeoisie declined, especially in Germany, France, and Spain. The great exception, on the Continent, was the Netherlands.

---

[1] Like all theorists, theorists of social history are reluctant to admit not only the importance of causal factors other than the ones emphasized by their own theories but also the importance of chance in the evolution of actual patterns. But the historical processes that produced the situations, created the problems, and shaped the attitudes reflected in that literature cannot be interpreted as many observers, Marxists especially, would like to interpret them, viz., as effects of the rise of capitalism. Even so far as they are traceable to capitalist evolution, they worked out in a way that differed radically from that prescribed by either capitalist interests or the capitalist mind. Let us note in passing how important this is not only for our own limited purpose but also for our diagnosis of the nature and *modus operandi* of the capitalist system in general—and even for our philosophy of history in general.

[2] I tried to illustrate this by a short analysis of an outstanding instance, the state of Louis XIV, in *Capitalism, Socialism, and Democracy*, ch. XII.

A third historic event of prime—and lasting—importance was the breakdown of the only effective international authority the world has ever seen. As has been pointed out, the medieval world was a cultural unit and, in principle at least, professed allegiance both to the Empire and to the Catholic Church. Although widely different views were held as to their true relation to one another, these two together formed a supernational power that was not only ideologically acknowledged but also politically invincible so long as they were united. According to the traditional view, this power was bound to wane as soon as the acids of capitalism began to dissolve the basis of medieval society and its beliefs. This is not so. Whatever those acids might have eventually done to that dual power, they had nothing to do with the actual breakdown that occurred long before those beliefs were impaired, simply because of the fact—which, from the standpoint of the basic process, was again accidental—that, for reasons which cannot be analyzed here, the empire was unable either to accept the supremacy of the Popes or to conquer them. A prolonged struggle that shook the Christian world to its foundations ended in a Pyrrhic victory of the Popes in the time of Frederick II (1194-1250). But in this struggle both parties had so thoroughly exhausted their political resources that it is more correct to speak of a common defeat of both: the Popes lost authority, the empire disintegrated. In consequence. medieval internationalism was at an end and the national states began to assert their independence from that supernational authority which had been formidable only so long as the Roman church co-operated with the 'temporal sword' of Germany.[4]

---

[3] This price revolution set in before the impact of the new gold and silver had made itself felt, and was at no time a function of their inflow alone. For our purposes, however, the popular opinion that it was may be allowed to stand as an approximation.

[(b) *Why the National States Were Aggressive*.] It must be left to the reader to develop the implications of all this. But it should be clear that it was the persistence of aristocratic rule, the access of ideally disposable wealth, and the breakdown of the supernational power of the Middle Ages—rather than anything derivable from the capitalist process itself—that explain not only the emergence but also the political physiognomy of the modern state. In particular, those facts explain why the modern state was 'national' from the first, and refractory to any supernational consideration; why it insisted and was compelled to insist on absolute sovereignty; why it fostered national churches even in Catholic countries—as instanced by Gallicanism in France; and above all why it was so aggressive. The new sovereign powers were warlike by virtue of their social structures. They had emerged in a haphazard way. None of them had all it wanted; each of them had what others wanted. And they were soon surrounded by new worlds inviting competitive conquest. Because both of this situation and the social structure of the epoch, aggression —or, what is the same thing, 'defense'—became the pivot of policy. In this fermenting world, peace was but armistice, war the normal remedy for political disequilibrium, the foreigner ipso facto the enemy—as he had been in primitive times. All this made for strong governments; and strong governments, chronically suffering from political ambitions that went beyond their economic means, were driven to increasingly successful attempts to make themselves still stronger by developing the resources of their territories and harnessing them into their service. This in turn explains, among other things, why taxation assumed not only a much greater but a new significance (see sec. 6 of this chapter).

---

[4] Perhaps it is misleading to stress the national element in this change. Though it shows well enough in the most important cases, those of France, Spain, and, earlier than anywhere else, in England, the true nature of the phenomenon will be more clearly visualized if we take account of the fact that in Germany and Italy, the countries that had been immediately subordinated to the imperial power, such states or 'principalities' emerged on a nonnational basis: it was not, at first, national feeling that welded those units but rather the interest of feudal princes who were strong enough to organize, to defend, and to rule a territory. Frederick II's own kingdom of Naples and Sicily is the earliest example, the Prussian state of another Frederick II the most telling. Popular support that might be linked up with capitalist interests and national sentiment came later and was as much the consequence of habit-forming conditions as it was a causal factor in subsequent developments. Nevertheless we shall, for convenience, go on speaking of the National State.

These facts, though fundamentally the same all over Western and Central Europe, produced somewhat different results according to the circumstances of different nations. Neglecting smaller countries, we find the main difference was between England and the Continent. In Germany, economic and political trends were broken by the course of events centering in the Thirty Years' War (1618-48), which created an entirely new situation and changed the political and cultural pattern of Germany for good. On the ravaged soil and in a population that had in places been reduced to less than 10 per cent, the princes, their soldiers, and their bureaucracies were, in the greater part of the national territory, practically all that was left of the political forces of the past. In Italy, alien rule and also devastation were responsible for a situation that differed from the German one only in degree. France and Spain did not have to go through experiences like these, but religious troubles and unending war efforts produced similar impoverishment in Spain and similar political and administrative conditions in both France and Spain.

In most of these countries—one exception is instanced by Switzerland and another by Hungary—the prince came to personify the state and the nation from the sixteenth century on. He succeeded in subjecting all classes to his authority—the nobility and the clergy not less than the bourgeoisie and peasantry, though the two former on the understanding that they should continue to hold a position of social and economic privilege. The wealth and power of this state was the unquestioned object of policy: maximum public revenue—for the court and the army to consume—was the purpose of economic policy, conquest the purpose of foreign policy. There should be no need for showing how concern for the welfare of the classes on which that social system fed entered into that policy: this welfare was not looked upon simply as a means to an end; it was an end in itself for many a great monarch or administrator, exactly as the welfare of his workmen was and is an end in itself for many a great industrialist; but it had to fit in with the given political pattern and with the given social system. All this—precisely where concern for the welfare of manufacturers, farmers, and laborers was most real—meant management of everything which in turn meant the rise of modern bureaucracy, a fact that is no less important than is the rise of the business class. The resulting economy was a Planned Economy; and it was planned, primarily, with a view to war.[5]

---

[5] This might be illustrated by the careers and policies of many great administrators of international and historical reputation. Comparative study of these men and their measures also brings out interesting differences and, above all, the fact that precisely the greatest of them cannot be said to have followed any consistent system of principles at all. One aspect of this will be mentioned presently in our text. We must confine ourselves to a brief comment upon Colbert, who has been and still is considered by many historians as the typical representative of that imaginary entity, the 'mercantilist system'—so much so that Colbertism is often used, especially in Italian, as a synonym of mercantilism. Jean Baptiste Colbert (1619-83), of bourgeois origin, was a civil servant who rose to be minister of finance (this, although various other

In England we observe the same tendencies. But there they were weaker and resistance to them was stronger because she was saved from the experiences that elsewhere broke the backbone of aristocracies and bourgeoisies alike. This was perhaps not merely a matter of a few miles of channel; but we may for brevity's sake adopt a theory which is only inadequate not untrue, namely, that it was the absence of actual foreign invasions and the rarity of serious threats of invasion that reduced the necessity for a military establishment—a navy of course carries much less political weight—and, in consequence of this, the power and prestige of the crown and of all the administrative agencies dependent upon the crown. The most obvious symptom of the difference this made, the survival in England alone of the old semifeudal constitution, is not in itself important for us. But all the more so is the fact that, throughout, the English state did not succeed in taking hold of national life as did the states elsewhere and that in particular the economic sector of national life, colonial venture included, remained relatively autonomous. Planning, if not absent, was more limited in scope—concerned principally with the relations of the English economy to Ireland and the colonies, and with foreign trade—and, what is still more to the point, was less strictly enforced than it was in most continental countries. But for the writers on economic topics this made less difference than we might expect. Some of them nevertheless reveled in visions of planning. And while some voiced the businessman's views, others voiced those of the bureaucrat. Also, we must never forget, if we wish to understand them, that practically all of these writers, in spite of what has just been said, consistently wrote with war and conquest in their minds. After all, notwithstanding her own relatively sheltered position, England was then going through the buccaneering stage of her imperialism.

[(c) *Influence of Special Circumstances on the Contemporary Literature.*] Unfortunately, the literature to be surveyed cannot be understood from the

---

offices were added from time to time, is the best way in which to describe his main function, which must, however, be understood to cover the affairs of industry, commerce, and agriculture as well) in the first period of Louis XIV's reign. He was an honest, able, and energetic administrator who knew how to raise money, intimidate creditors, improve administrative and accounting methods, stimulate industry, build palaces and harbors, develop the navy, and so on, though he was distinctly unlucky in the execution of his larger plans, e.g. colonial enterprise, the history of which shows that the wastes of public planning may easily surpass anything that, on the score of wastefulness, can be charged to private enterprise. There is no reason to extol his achievement, especially to see in him the oversized champion of some great principle, as did some of his admirers. See on Colbert and his immediate successors, C. W. Cole, *Colbert and a Century of French Mercantilism* (1939), and *French Mercantilism, 1683-1700* (1943). In his review of the former book, in *Economic History* (February 1940), Sir John Clapham voiced a reaction against unintelligent admiration that is almost amusing in its vehemence: according to him, Colbert had 'no single original idea' (which is true but beside the point in the appraisal of an administrator) and was a 'big stupid man,' tyrannical, brutal, fussy. For the period preceding his administration, see J. U. Nef, *Industry and Government in France and England, 1540-1640* (1940).

facts referred to alone. Much of it is conditioned by individual situations in individual countries that writers took for granted, and by individual issues that arose from these situations. Even books and pamphlets that do not deal with questions raised by an individual bill or practice can hardly be appreciated without full knowledge of the particular national patterns as seen by their authors. A lengthy list of mistakes in interpretation and appraisal that were committed, especially by nineteenth-century 'liberal' critics of that literature but also by later ones, could be compiled to illustrate this truth. But there is nothing we can do about it here[6] beyond offering the following generalities. A few other facts will be added where necessary as we go along.

I. All the economics of those times—with the possible exception of the Dutch branch of it—was written in and for countries that were poor. This holds without exception if 'poor' is equated with 'undeveloped.' All European countries stood at the beginning of their industrial and even of their agricultural careers and everybody realized this. With us, economic expansion is primarily linked with new wants and methods; that age, however, had practically inexhaustible possibilities before it with existing wants and technologies, in addition to what it was coming to expect from technological progress and from conquest. But our proposition applies in a different sense and with added force to the great continental countries that in the second half of the seventeenth century were faced also with an immense reconstruction problem. They were poor even relatively to what they had been in the sixteenth century. It should be clear that in such conditions policies and reasonings may have had meaning that seemed mere nonsense to observers who viewed them from the standpoint of nineteenth-century conditions.

II. Throughout, all countries—even England—were predominantly agrarian. Their economic problems were primarily agrarian problems, the masses of their people were agrarian masses—peasants, farmers, agrarian laborers. In the sixteenth, seventeenth, and eighteenth centuries, this agrarian world underwent changes that revolutionized it completely: economic historians rightly speak of an agrarian revolution, or rather of several agrarian revolutions. This phrase indicates two distinct, though of course related, types of change that reinforced each other and would have broken down the framework of medieval society even if nothing had happened in the industrial sector. On the one hand, there was a long series of changes in the technologies of all branches of agrarian production—this process gained momentum in the eighteenth century but started at the beginning of the sixteenth. On the other hand, there was, in sympathy with the technological revolutions, a process of organizational change that turned medieval manors into grain, wool, and meat factories and destroyed the old relations between lords and peasants or farmers.

---

[6] It is impossible, even, to give an annotated reading list, for it would fill a volume. Going to the other extreme, therefore, I shall mention but two well-known standard works which in any case are, or ought to be, in every student's hands: E. F. Heckscher's *Mercantilism* (1931, English trans. by M. Shapiro, 1935) and P. Mantoux's *The Industrial Revolution in the Eighteenth Century* (rev. ed., 1927, English trans. by M. Vernon). These works contain the bulk of what the reader ought to know.

It must suffice to mention the chief English form of this type of change, Enclosures. Governments and, accordingly, writers took two characteristically different attitudes to this change. On the Continent, and especially in Germany, governments made a determined and largely successful effort to save the peasants and to turn them eventually into a class of small landowners. In England, the land-owning and land-tilling yeomanry was allowed to disappear and, deserted-village emotionality notwithstanding, the large estate prevailed, not however as a producing unit but as a unit of administration that left production to the workman-capitalist, the farmer.

III. But it is by no means surprising that manufacturing and international trade, comparatively insignificant though they were, attracted more literary attention than did agriculture. They were the young children and, moreover, the children on whom the future of the family was mainly felt to depend. Also, they had more motive and opportunity than had the landowners and farmers to spill ink on their own behalf. For economics this simply meant that there were more 'industrial and commercial' than 'agricultural' economists. But the existence of these two groups of writers was primarily a phenomenon of division of labor as it is now: their very natural antagonisms should not be sublimated into antagonisms between philosophies either of life or of economics except in cases—the only important one is that of the physiocrats (see below, ch. 4)—where there is some provable warrant for it.

Large-scale enterprise—large relatively to environmental standards—emerged, to a significant extent, in the fourteenth century in Italy, in the fifteenth in Germany, in the sixteenth (under Elizabeth) in England, first in the financial and commercial sphere and then in the sphere of production. But, substantially, the manufacturing industry that economists beheld and reasoned about was all along the manufacturing industry of the artisan (still organized in craft guilds), of the 'master' of domestic industry, and of the owner-manager of factories that were few and mostly quite small. In Western Europe, especially in England, this changed (significantly but not fundamentally) in the Industrial Revolution of the last decades of the eighteenth century, but the full consequences did not reveal themselves before the first decades of the nineteenth. Many authors, occasionally even A. Smith, class the manufacturer with the workman. No author, not even A. Smith, had any very clear idea of what the processes really meant that led to what economic historians have dubbed the Industrial Revolution. A. Smith felt that the corporate form of industry was an anomaly except in such cases as canals and the like. To him and his contemporaries big business still meant commercial and financial big business—colonial enterprise particularly. And they looked upon it much as modern economists look upon any kind of largest-scale business, namely, with feelings of resentful distrust.

IV. This industrial and commercial evolution was characterized, almost until the end of the period under discussion, by 'monopolistic' policies and business practices that were one of the chief topics of the economic literature of that period and have been visited with sweeping condemnation by economists and economic historians from A. Smith to this day. By 'monopolistic' public policy and private business practice, we mean measures and forms of behavior intended to secure profitable 'vent' for the products or services of an individual or group by (1) keeping the foreigner out of national and international markets—which, so long as national territories had not become economic units, often included keeping out the producers and traders of the neighboring town or district; (2) keeping out of a trade, so far as possible, all connationals other than the favored individual or group—for instance, keeping retailers out of the merchant's business; (3) restricting the output of the favored individual or group itself and regulating its distribution between markets. Let us stay for a moment in order to analyze, in the light of the preceding considerations, the reasons for the prevalence of this policy and practice.

First, we might expect that, if fullfledged capitalism had suddenly burst upon the world and if it had been permitted to unfold without being distorted by the factors referred to, both business behavior and public policy would have been from the first what they became in fact, for a time, in the nineteenth century. That is to say, we might expect that in this case there would have been, in countries that were so poor in goods and so rich in possibilities, an onward rush of competitive enterprise. This expectation would be, however, only in part justified. Poverty is a bad customer, and normal risks of doing business are greatly increased in an environment where the wealth from which demand is to proceed has not only to be attracted but created. In business as elsewhere, forward strategy very often requires defensive tactics as a complement, though most economists of all ages stubbornly refuse to see this. But under conditions in which long-run advance was inevitably slow, each stage had to be safeguarded with particular care in order to gain means and time for advancing beyond it. It is quite natural that the observing historian should be much more impressed by the practices and policies that aimed at protective restriction, which dominate the scene at every point of time, than by the picture of the process over time.[7] But it is true nevertheless that even an ideally rational government, actuated by the sole motive of fostering industrial development, would have had to grant privileges of monopoly in many cases in which enterprise would not have been possible at all without it, and that, in others, it would have had to permit monopolistic practice on the part of the businessmen concerned. This holds, of course, with added force for those countries that had been ravaged by war, such as Germany, where only prospects of abnormal gain could call forth entrepreneurial effort from a population immersed in misery and despair.

Second, however, capitalism did not burst upon a world that was a blank: it grew by slow degrees from a pre-existing pattern dominated, in the respect under discussion, by the spirit, institutions, and practice of craft guilds. New products, new methods of production, and new forms of enterprise are resisted by any environment; but in these centuries there was in existence a legal machinery of resistance that worked automatically. This bears upon our topic in two ways. On the one hand, legislation and administration in all countries, under pressure from craft guilds and in their interest, subjected the newer 'free' enterprise to various regulations that spelled restriction of output. On the other hand, though these regulations have no roots in the capitalist system, but spell distortion of it, the merchants, masters, and so on who were affected by them naturally made the best of a bad business and organized themselves in a similar way. There were several reasons—besides the gains to be expected from restrictive regulation—why this came easily to them: the merchants and masters were themselves the products of a world in which organization and corporate action was the recognized thing and they had no objection to accepting 'ethical' and religious codes, enjoining standardized behavior, prayer meetings included. They lacked standing and political weight so long as they acted as individuals, whereas each Worshipful Company was a political power; and, in the most important case of overseas trade, the need of providing for physical protection and aggression—there were such things as joint stock companies formed for no other business than piracy—was a motive that was bound to throw traders together and to invite corporate action in other respects also. The Chartered Company, not a trading company itself but rather the organizational shell for the trade of its members, was, partly in opposition to, and partly in alliance with, the medieval Staple System (*jus emporii*), the obvious answer to all these needs and the natural instrument for making the most of the opportunities afforded by the protectionism of the age.[8]

---

[7] There is no better illustration for this attitude than the late George Unwin's brilliant essay on the Merchant Adventurers in *Studies in Economic History* (1927). Professor Heckscher (op. cit.), with less reluctance to penetrate beyond that short-run view, formalized the situation into the two polar concepts of 'hunger for goods' and 'fear of goods,' which do not express well the economics of it.

Third, the governments of the national states had particular motives of their own for creating or favoring more or less 'monopolistic' organizations or positions. One of these motives has been mentioned already, the reconstruction motive. Another was the prospect of personal gain for the rulers—Queen Elizabeth participated personally in the gains (and losses) of 'monopolistic' ventures, even in the proceeds of downright robbery. The same great monarch offers outstanding examples of the method of providing for favorites by granting them letters patent of monopoly. Also, 'monopolist' organizations were sponges, which it was much easier to squeeze than it would have been to squeeze a large number of independent entrepreneurs. And, finally, given strong governments, such organizations are not only easier to exploit but also easier to manage: their own administrative organs are so many ready-made handles for governments to seize. This aspect will appear in its full importance if we remember the nature of the policy of those governments for whom measures concerning trade were just one of the instruments of aggressive power politics: to force trade in one direction, to stop it entirely in another, was in some cases almost as effective as was a campaign; moreover, colonial companies of different nations might wage war upon each other while the respective national governments were officially at peace.[9]

---

[8] It is unfortunate that we cannot go more fully into the meaning and structure of both. Reference to Professor Heckscher's work must suffice. One point must be mentioned, however. The staple system has been called medieval because it grew out of the pattern of craft guild industries in the thirteenth century (it had spread to England by the time of Edward III, as his ordinance on staples shows). But, adapting itself to changing conditions, it survived, as a general method of regulating international trade through the greater part of the period under survey, in Venice even until the Napoleonic occupation. In England, the loss of Calais in 1558 killed one form of it but in another form it continued to prevail: in fact, it was fully developed only by the Navigation Act of 1660 (for the policy of the Navigation Acts is but a special type of staple policy) and by the Staple Act of 1663.

Very naturally, the public at large resented being exploited in any of those ways and for any of those purposes without troubling to distinguish between them and without asking the question whether or not there were any compensating advantages to those practices in some cases, for instance, in cases where certain articles could not have been provided at all without them. The copious literature on the subject—the reader knows most of it if he knows the corresponding popular literature of today—simply reflected this resentment and rarely[10] went beyond denouncing favored individuals and groups, the East India Company and the Merchant Adventurers being, in England, the most popular targets. Even the businessmen joined the fray against restriction and privilege in almost every case that was not the writer's own: everyone was the sworn enemy of everyone else's privilege. Thus, most searching analysis was produced principally by 'special pleaders' who defended individual cases.[11] Let us recall, however, from Part I that the motives of the analyst are not relevant to the question whether his facts or arguments are or are not true, valuable or not valuable, and that the presence of 'interested motive,' however effective its revelation may be in popular discussion, no more invalidates the reasoning that proceeds from it than its absence avails to validate a man's reasoning. For us, the special pleader's facts and argument are just as good or bad as those of the 'detached philosopher,' even if he exist.

---

[9] Again we may appeal to Dr. Unwin's lectures (op. cit.) for illustration of a kind of 'liberal' criticism of such attitudes and policies that tends to obstruct historical understanding even where it asserts nothing that is not correct. He offers strong reasons for believing that England did not net any national advantage from either her 'monopolistic' policies or her buccaneering (though it is going rather far to assert that robbery of treasure was not nationally remunerative because it destroyed the essential thing, credit) and, so far as this goes, errs only by ignoring the long-run aspects of 'monopolistic' restriction and 'monopolistic' gains. But his case, were it even stronger than it is, must remain inconclusive precisely because it is the case of the nineteenth-century liberal. The pattern of sixteenth and seventeenth-century behavior must be considered from the standpoint of sixteenth and seventeenth-century data *and men*. If we do this, even from a purely economic angle, irrationality is not so obvious. But in a situation of perennial warfare, where harming the other fellow is an end in itself, purely economic considerations are obviously inadequate. And there is something else. In discussing historical situations we must always distinguish between the principles underlying a form of behavior and the efficiency with which they are acted upon. This is very important. A. Smith, for instance, argued as much against the corruption and mistakes incident to the state management of his own and earlier times as he argued against state management per se. And so do we: the present-day argument against socialism or against extension of bureaucratic control is as much an argument from inefficiency to be expected in the application of the principles of socialism or control as it is an argument against these principles themselves. Both types of argument have their place but they must be kept separate.

[10] The most important instance is the 'discovery' of oligopoly (see below, ch. 6, sec. 3c).

Explanations too obvious to detain us may be offered for the fact that the public's reaction to restrictive practice was much stronger in England than it was on the Continent: to mention a symptom, free trade, which in the seventeenth century meant, among other things, abolition of the staple system or abolition of the chartered companies or at least every trader's right to become a member of the latter, found support in parliament and a fairly sweeping bill against restrictions of trading—not, of course, for free trade in the later sense of the term—was introduced, though not carried, as early as 1604. But there is another point of difference that is of considerable interest to us. The reader may have observed that, however objectionable to the man in the street most of the restrictive practices and legislative measures may have been, they did not create monopolists in the strict sense of Single Sellers,[12] and did not result in specifically monopolistic pricing. Nevertheless, the general outcry against them all was against monopoly. The reason is not far to seek. Though the English public of Queen Elizabeth's time can hardly have been influenced by the fact that monopoly had been stigmatized already by Aristotle and the scholastics, it harbored old resentments, dating from the Middle Ages, against corners and the like. These resentments flared up into fury when Elizabeth and James I adopted the practice of creating in large numbers what were in fact genuine monopolies and, moreover, monopolies that presented, in most cases, no redeeming features. In the struggles over these, the word Monopoly became loaded with emotion, a bugbear for all time to come, that was in the mind of the average Englishman associated with royal prerogative, favoritism, and oppression; and Monopolist became a term of opprobrium. But once a word has acquired an emotional value, positive or negative, that guarantees automatic reaction from almost anyone who hears or reads it, speakers and writers will try to exploit this psychic mechanism by applying the word as extensively as possible. And so monopoly came to denote almost anything that a man disliked about capitalist practice. This emotional attitude naturally spread to the United States the more readily because a large percentage of English emigrants to this country were, for other reasons, strong opponents of the Tudor-Stuart regime. It has survived, and has powerfully influenced public opinion, legislation, and even professional analysis to this day, both in England and the United States.[13]

---

[11] One of the best of those performances may be mentioned by way of example: John Wheeler's *Treatise of Commerce, Wherein are shewed the Commodities arising from a well ordered and ruled trade, such as that of the Societie of Merchants Adventurers is proved to be. Written principally for the better Information of those who doubt of the Necessarinesse of the said Societie in the State of the Realme of England* (1601), and, so we may add, in view of impending hostile legislation.

[12] Monopoly in the strict sense denotes the position of a single (individual or corporate) seller, who faces a demand schedule that is given to him independently of his own action and of the action of sellers of competing goods. The exclusive right to sell port wine may, in the conditions of sixteenth and seventeenth-century England, be considered as a good practical approximation to strict or genuine monopoly, although, in general, a seller of port wine could not expect the demand schedule to stay put when the prices of similar beverages varied. But the big trading companies such as the Merchant Adventurers were not monopolies in this sense, for though they regulated the business of their members they did not in general fix prices. The reason why economists should confine the term Monopoly to the 'genuine' case defined is that their theory of monopoly price applies to this case only—or, to put it differently, because specifically monopolistic price policy is possible in this case only—so that nothing but confusion can result from any wider definition.

Most of what has been said in this section indicates definite patterns of behavior that seem to invite sublimation into 'principles.' This has in fact been done, and the phrases Mercantilism, Mercantile System, Mercantilist Policy have been coined, first by hostile critics, to denote the result. Nevertheless, I have tried to avoid using them so far. The reason for this will be explained in Chapter 7, where we shall make Mercantilism—phrase and reality—our central theme. Meanwhile I wish to ask my readers to forget all they may know about it and to peruse what follows with an open mind, that is, with a mind unbiased by unhistoric preconceptions.

[2. The Economic Literature of the Period]

We shall now try to classify the unwieldy material from which we are to extract more or less significant products of analytic effort. This is a difficult task. Even in our own day economists are not always of one mind as to which performances do and which do not measure up to professional standards. But we are dealing with a formative period in which there were no professional standards, not, at all events, before the Classical Situation at the end of it. Moreover, the field itself was undefined and, by virtue of this fact alone, much wider than it is now: it covered, for instance, technology. However, in order to reduce our task to manageable proportions, we shall right away exclude from consideration certain bodies of literature that are also excluded by modern practice, though we must not conceal from ourselves that, in so doing, we may be excluding pieces of analysis that are not inferior to some we include without question. This operation on our material is performed in the four paragraphs which follow.

---

[13] This explanation seems to be more convincing than the usual general references to a specifically English love of freedom and fair play or to a specifically continental propensity to accept regimentation and the like. An English example that will illustrate both the phenomenon to which I wish to draw attention and its persistence is afforded by the nineteenth-century English champions of free trade in foodstuffs, who loved to refer to their opponents as 'monopolists' although neither the English farmers nor the English landowners were monopolists in any meaningful sense of the term. Even Sir Robert Peel, who occasionally displayed a sense for demagogical values, used the phrase in his speech in the Commons delivered on the defeat of his great ministry in 1846.

[(a) *The Material Excluded.*] I. In the sixteenth century and even later, *Oeconomia* still meant household management. This type of literature seems to have been extremely popular. The no doubt unreliable method of browsing among books of this sort did not yield anything that would qualify for notice in this history. But two samples may be mentioned: first, the famous *Oeconomia ruralis et domestica* (1593-1607) by Johann Colerus, which lived for over a century and contains all sorts of advice about housekeeping, including farming, gardening, and domestic medical practice; second, *L'Economo prudente* (1629) by B. Frigerio, who defined *economia* as 'a certain prudence with which to govern a family' (ch. IX, for instance, deals with the *governo* of one's wife) and might conceivably interest some economists because it attempts to describe national economic behavior—in fact its concept of the *economo* is a common-sense forerunner of the concept of the Economic Man. Similarly, B. Keckermann, *Systema disciplinae politicae* (1606) defined *Oeconomia* as *disciplina de domo et familia recte dirigenda.*

II. Much more important is the literature on accounting and commercial arithmetic, which shades off into the neighboring literature on business management, business law, commercial geography, and business conditions in various countries. A few examples will characterize the contents of these literatures, which we exclude, although little pieces of purely economic analysis do occur in them. Fra Luca Paccioli's *Summa de arithmetica, geometria, proportioni e proportionalità* (Venice, 1494) contains, besides the ordinary commercial calculations of interest, bills, exchanges, and so on, also an exposition of double-entry bookkeeping. The first German book on double-entry bookkeeping that I have seen is W. Schweicker's *Zwifach Buchhalten* (1549). Such texts became common in the sixteenth and seventeenth centuries. So did guides to commercial practice in the trading centers of Europe. One of the earliest and most famous of these which the reader may look up in Cunningham's *Growth of English Industry and Commerce* (5th ed., vol. I, pp. 618 et seq.) was F. B. Pegolotti's *La Pratica della mercatura* (about 1315). The seventeenth-century publications of this type often contain rudimentary economic arguments. See, for example, John Roberts, *The Trades Increase* (1615), and Lewes Roberts, *The Merchants Mappe of Commerce* (1638). In the seventeenth and eighteenth centuries we find, on the one hand, a rich crop of monographs, especially on banks, some of which will have to be noticed later on, and, on the other hand, comprehensive compilations. We must mention Jacques Savary's *Le parfait negociant* (1675), which proved its vitality by going through new editions until 1800 and seems to me to repeat, on a larger scale, the performance of G. D. Peri, *Il Negotiante* (1638-65) and the still earlier one of B. Cotrugli Raugeo, *Della Mercatura e del mercante perfetto* (1573); and Savary's son's (Jacques Savary des Bruslons) *Dictionnaire universel du commerce* . . . (finished and published by his brother Philémon-Louis, 1723-30). Malachy Postlethwayt's *Universal Dictionary of Trade and Commerce* (1751-5), though based upon the latter, is by no means a mere translation of it, as has sometimes been asserted (on the differences, see E. A. J. Johnson, *Predecessors of Adam Smith*, 1937, Appendix B. The same author, in the same work, Appendix C, also reduced to its proper proportions the charge of plagiarism that has been frequently leveled against Postlethwayt, though the case remains bad enough). Neither of these dictionaries is, however, primarily concerned with what we call economics. Both were meant to serve the merchant's practical needs and deal with economic problems only incidentally. This is the difference in principle that, apart from the statistical complement, separates these ventures from later similar ones, especially from McCulloch's *Dictionary, Practical, Theoretical, and Historical of Commerce and Commercial Navigation* (1832).

III. It is with misgivings that I also exclude the literature on husbandry (farm management, agrarian technology) and forestry; the exclusion of other technological material need not cause qualms, though some writers, for instance writers on the technological aspects of mining, also dealt with economic subjects (see G. Agricola, *De re metallica*, 1556, later translated into German, an apparently highly successful treatise). The development of the literature on husbandry during the period may be briefly sketched as follows. In the thirteenth century there was a group of English writers—nobody has so far been able to link them up with either predecessors or immediate successors—who produced several remarkable works on estate management and farming (translated from Norman French and critically edited for the Royal Historical Society by Miss Elizabeth Lamond, 1890); it suffices to mention a treatise on *Husbandry*, written before 1250 and attributed to Walter of Henley. Disregarding this group, we find active interest in these matters from the fifteenth century on, when new editions of the Roman agriculturalists (*Scriptores rei rusticae*, the earliest edition I have seen is dated 1472), Columella in particular, seem to have been eagerly demanded. A new spirit of commercialism in agriculture—associated with the upheavals in the social structure of the countryside—then produced everywhere a literature that aimed at teaching those new methods of production, the introduction of which is usually referred to as the Agrarian Revolution. In England, there is a continuous development from Fitzherbert's *Boke of Husbondrye* (1523), to Weston's *Discours of Husbandrie used in Brabant and Flanders* (1650), to Worlidge's *Systema agriculturae* (1669), Mortimer's *Whole Art of Husbandry* (1707), and Jethro Tull's *Horse-Houghing Husbandry* (1731), which stands at the fountainhead of an outburst of literary activity that lasted throughout the eighteenth century and, in a sense, culminated in Arthur Young's copious writings (see, e.g., his *Rural Economy*, 1770, and his periodical, the *Annals of Agriculture*). This literature dealt with a wide range of topics from enclosures to drainage, drilling, crop rotation, turnips and clover, and cattle breeding. On the Continent, the Dutch led in agricultural practice, but the Italians in the literature of the subject. Let us notice as a forerunner, as yet substantially under the influence of the ancients, P. de Crescenzi (*Opus ruralium commodorum*, I only know the edition of 1471) and then A. Gallo (*Dieci giornate della vera agricoltura*, 1566), G. B. della Porta (1583), and especially the strikingly original Camillo Tarello (*Ricordo di agricoltura*, 1567, but I only know an edition of 1772), who in important points anticipated the development of almost two centuries. Of German contributions, we shall notice Heresbach's *Rei rusticae libri quatuor* (1570, first translated into English, 1577) and the work of Colerus (see above). Developments were then interrupted, but were resumed by the end of the seventeenth century to run on steadily to the writings on rural economy of J. C. Schubart (1734-87), whom Emperor Joseph II ennobled with the significant title of 'Cloverfield.' The Spaniard, G. A. de Herrera (*Libro de agricultura* . . . new ed. 1563), and the Frenchmen, Charles Estienne (*L'Agriculture et maison rustique*, 1570; Italian trans. 1581; I do not know the original) and Oliver de Serres (*Théâtre d'agriculture*, 1600) should also be mentioned. This attempt to locate the early landmarks must suffice, although this literature contributed considerably to the formation of some of the habits of thought that are most characteristic of modern economics. The same is true of the literature on forestry, into which I have not been able to go at all. It is worth noting, however, that forestry remained a recognized division of German treatises on general economics right into the nineteenth century.

IV. Description by travelers of the economic conditions they observed in foreign and even in their own countries forms an important part of the economic literature in the period under discussion, owing to the absence of regular reporting by permanent agencies. This method of reporting on facts and interpreting them was done on very different levels that range from stray observations to careful analyses, occasionally involving considerable bits of theory. Neglect of this literature is apt to distort seriously our picture of the economics of those centuries and in particular to hide the full extent of the fact-finding work that was actually done. Nevertheless, we have no choice but to exclude this literature. It must suffice to mention two famous English samples which will repay perusal: Sir William Temple's *Observations upon the United Provinces* (1672; 3rd augmented ed. 1676), which presents conditions in the Netherlands from the standpoint of a definite philosophy of wealth (that centers on 'frugality and industry'), and Arthur Young's reports on his various tours and travels (most important in this connection: *Travels . . . with a view to ascertaining the Cultivation, Wealth Resource, and National Pros-*

perity of the Kingdom of France, 1792), which contain a lot of what might be termed 'theory in action.'

[J. A. S. intended to have this discussion of the Excluded Material set up in small type as being of interest only to the specialist. Many of the books mentioned he examined in the Kress Library (Harvard School of Business Administration), which seemed both to him and to the Editor to be a kind of scholars' Paradise.

To Professor Alexander Gerschenkron I owe the information that Georg Agricola's *De re metallica* (mentioned above, III) was translated into English by Herbert Clark Hoover and Lou Henry Hoover (1912; new ed. 1950).]

[(b) *The Consultant Administrators.*] The authors of the remaining material we shall divide into two clearly, if only broadly, distinct groups. We shall call them the Consultant Administrators [1] and the Pamphleteers. Among the Consultant Administrators, teachers and writers of more or less systematic treatises form a subgroup that is relatively easy to delimit. In that paradise of bureaucracy there was, of course, a steady demand for the instruction of young men who were preparing themselves for the public-service career—or of older men who wished to improve their equipment—particularly in Germany and Italy. In the course of the eighteenth century, professorial chairs began to be provided for the teaching of what was described, in Germany, as Cameral Science or Science of the State (*Staatswissenschaft*) and what may be more accurately described as Principles of Economic Administration and Policy (in German, *Polizeiwissenschaft*).[2] Thenceforth those treatises were to a large extent simply textbooks and the products of academic lectures. The same need, however, had asserted itself much earlier, and systematic treatises of pedagogical interest had been written in all continental countries long before economics as a distinct field received the official recognition implied in the foundation of those professorships.

---

[1] This term roughly covers the same type as does the Spanish term *políticos.* In the German literature the word in general use is *Cameralist* or *Kameralist* (derived from the territorial treasuries, the *camerae*). But it carries a misleadingly narrow association and in addition would not serve our purpose, which is to label a group that includes the German type but is not confined to it. Histories and bibliographies of German Cameralist literature were published as early as 1758 by J. J. Moser and 1781-2 by K. G. Rössig (*Versuch einer pragmatischen Geschichte der Ökonomie, Polizei und Kameralwissenschaft*). Much help has been derived from R. von Mohl, *Geschichte und Literatur der Staatswissenschaften* (1855-8) and from the comprehensive bibliography, *Bibliographie der Kameralwissenschaften* (1935-7) by Miss Magdalene Humpert, who lists about 14,000 items, most of which fortunately do not come within the range of this history. Also see K. Zielenziger, *Die alten deutschen Kameralisten* (1914), and Louise Sommer, *Die österreichischen Kameralisten* (1920-25). An American book may be added: A. W. Small, *The Cameralists* (1909).

[2] See especially Wilhelm Stieda, *Die Nationalökonomie als Universitätswissenschaft* (1906). We may mention the foundation of the chairs in the Universities of Halle (1727; which immediately evoked derogatory comment as regards the competence of the newly appointed professors), of Uppsala (1740), and of Naples (1754, chair of 'economia e commercio' founded for Genovesi). We know, of course, that the teaching of economics must not be dated from these. The scholastic and the natural-law philosophers had taught economics before, both in law and in moral-philosophy courses. And the training of civil servants also antedates the eighteenth century. In the Universities of Naples (founded 1224), Oxford, Prague, Cracow, Vienna, Salamanca, and others its beginnings go back to the thirteenth and fourteenth centuries, and in the sixteenth it was second in importance to the training of clergymen in Marburg, Königs-

But from the fifteenth century on, first in Italy then elsewhere, public administrators of all ranks and types—great noblemen as well as humble drudges —began to put on paper their ideas about how the government and the economy of their countries should be run and especially how their finances should be managed. These administrators were practitioners, familiar with the business of governing, and most of them were laics. Their books, reports, and memoranda thus differ characteristically from the works of the schoolmen and the philosophers of natural law. It is true that they also differ from those of the teachers.

The practitioners lacked the systematic habit and the erudition of the academic professional, though they made up for these shortcomings by their command of facts and the freshness of their outlook. Nevertheless we shall include them with the teachers in our group of Consultant Administrators. After all, they were mostly public servants writing for other public servants. We must, however, go still further. We must also include a number of men who were not public servants but who made, in the same spirit as did these, the public cares their own or, doing still better, wrote in the genuine spirit of scientific analysis—businessmen, professors of sciences other than economics, private individuals of the most varied backgrounds and stations. Thus we get, alongside of the professional subgroup, another one that forms a unit not in any sociological sense but by virtue of the nature of its performance. From it proceeded much of the most important—especially the most original—work of the period. And this work, though rarely systematic in form, was very often systematic in substance. In England, such publications became so numerous in the seventeenth century that they constitute an easily recognizable standard type; there was also a standard title for them, *Discourse of Trade*. But they were not confined to England, though elsewhere there was no standard title except, perhaps, in the case of the French *Éléments du Commerce* of the eighteenth century. We shall call these books Quasi-systems. It was in them that 'general economics' first took *independent* shape.

[(c) *The Pamphleteers.*] The Pamphleteers were a mixed crowd—projectors of banks, canals, industrial and colonial ventures; special pleaders for or against some individual interest, such as the Company of Merchant Adventurers or the East India Company; advocates or foes of a particular measure or policy; planners—often cranks—with pet ideas; and men who do not come within

---

berg, Würzburg, and Graz. Moreover, there were professorships of 'statistics' in the seventeenth century. It may be of some interest to note that in England and Scotland no chairs of economics per se were founded in the eighteenth century. Professors of agriculture were, however, appointed in Edinburgh, 1792—where the chair of Political Economy actually dates from 1871—and in Oxford, 1796—where it dates from 1825.

any of these categories but simply wished to clear up some issue or to present a piece of analysis. All of them flourished in all countries owing to the rapid increase of the opportunities for printing and publishing. Newspapers also, rare ventures in the sixteenth century, became plentiful in the seventeenth and, for the eighteenth, 170 papers and periodicals that published economic material have been listed for Germany alone.[3] But England was the classical home of the pamphlet, as we should expect. For nowhere else was there so strong an incentive for anyone with an axe to grind to try to influence public opinion.

It is with these pamphleteers that the difficulty pointed out at the beginning of this section becomes most serious. So far as their writings simply reflect the conditions, humors, struggles, and idiosyncrasies of their day, they are of course very interesting for the economic historian and the historian of economic thought, but of no interest for us. In a report on the present state of economics nobody would think of including the 'popular' or what Marx termed the 'vulgar' economics of our own time. But up to, say, 1750 no such distinction is possible. All the 'scientific' economics there was consisted in the small nucleus contained in the systems of the philosophers of natural law, and with this any intelligent businessman who knew his facts was able to compete successfully without having to acquire any particular technique. Moreover, the Pamphleteers slowly evolved the primitive technique they needed. Some of them produced tracts of strictly scientific character. And the economics of the First Classical Situation owes a considerable debt to them. So we cannot afford to neglect them. But every one of us must, within his individual command of the material,[4] rely upon his own fallible judgment of quality.

3. Sixteenth-Century Systems

Again we take the *Wealth of Nations* as our point of orientation. In the preceding chapter we looked upon A. Smith as a philosopher of natural law. In this one we shall look upon him as a Consultant Administrator. On our way toward him I shall try to avoid confusing and empty enumerations and introduce as few names as possible. But a small number of major or particularly representative performances will, either in this or in the subsequent chapters, be discussed in sufficient detail to give an idea of their nature and significance. Taking the period as a whole, I think that first honors should go to Italy. If there could be any point in such a statement, we might say that economics was primarily an Italian science until the last quarter of the eighteenth century. Spain, France, and England divide second honors, though in very different proportions at different times. The rest of this chapter is devoted chiefly to the first, or professorial, of the two subgroups into which we have divided the Consultant Administrators, though it will be necessary to cast some glances also at authors of quasi-systems. The reason for this arrangement is not that the works of the former type are of commanding interest or importance. On the contrary, no other group produced, among more inspiring ones, books of such unspeakable tedium. Rather we deal with them first in order to get them out of our way.

---

[3] This is, of course, a total for the century. Many of these papers and periodicals were very short-lived. Perhaps not more than 10 per cent of that total existed at any one time. Nor were they equal to the French in quality. The specifically economic journal is in fact a French achievement. The first of this type was the *Journal Oeconomique* (1751); then followed the *Gazette du Commerce* (1763), which the government bought and supplemented by the *Journal de l'Agriculture, du Commerce et des Finances* (1764), which became for a time the organ of the physiocrats.

[4] So far as I know it, and so far as contributions to economic analysis are concerned, the European pamphlet literature of the sixteenth, seventeenth, and eighteenth centuries can be reduced to less than two dozen items. The reader must not overlook, however, that we class with the Consultant Administrators several names that other writers would class with the Pamphleteers.

[(a) *The Work of Carafa.*] In the late Middle Ages economic history already affords ample evidence of what, in view of our own performances, we are bound to call a high level of insight into the practical problems of economic policy. An often-quoted English instance[1] will suffice to show this. What we should call 'hearings' on the outflow of money from England and other currency problems were held in 1382. The reader can easily satisfy himself that what the experts examined had to say makes perfectly good sense and does not differ substantially from what we should expect to hear from similar experts under similar conditions, though it would no doubt be couched in more sophisticated phraseology. If documents such as these reveal the presence of a certain amount of analytic power, there are also indications of the presence of interest in the collection of facts: Étienne Boileau's *Livre des métiers* (about 1268),[2] a compilation of the regulations concerning the trades of Paris, is a landmark of this type of research which gathered momentum from the sixteenth century on. Literary effort of the type to be discussed in this chapter also goes far back—in a sense to St. Thomas' *De regimine principum* and to the *English Speculum regis* (ed. by Moisant, 1894) and other works of the thirteenth and fourteenth centuries, such as Aegidius Colonna's *De regimine principum libri*, or Fra Paolino's *Trattato* (ed. Mussafia, 1868), or Petrarch's *De republica optime administranda.*

From this literature emerged, in the fifteenth century, a work so superior to all that had been written before that we may fittingly head our list of Consultant Administrators with its author, though he was primarily a practical one, the Neapolitan count and duke, Carafa.[3] The range of his ideas may be indicated by some of his recommendations. He wanted to see a balanced budget that would have plenty of room for welfare expenditure and avoid the necessity of resorting to forced loans—which he compared to robbery and theft—and the like; definite, equitable, and moderate taxes that would not drive capital from the country or oppress labor, which is the source of wealth; business left alone, though he added that industry, agriculture, and commerce alike should be encouraged by loans of money and in other ways; foreign merchants made comfortable because their presence is most useful to the country. All this is no doubt excellent sense and remarkably free from any definite errors and prejudices. But it is equally free from any attempt to analyze. The normal processes of economic life harbored no problem for Carafa. The only problem was how to manage and improve them. In particular we must not suspect a theory of value behind that passage about labor's being the source of wealth. Such questions exercised the nimble minds of his scholastic contemporaries. But they never occurred to that soldier-statesman.

---

[1] See 'Opinions of the Officers of the Mint on the State of English Money, 1381-2' in *English Economic History: Select Documents* (compiled and ed. by A. E. Bland, P. A. Brown, and R. H. Tawney, 1914), pp. 220 et seq.

[2] Edited by Depping in *Documents inédits sur l'histoire de France* (1837).

[3] Diomede Carafa (1406-87), *De regis et boni principis officio* . . . (ed. used, 1668; I have not seen the original, written in Italian in the seventies of the fifteenth century). Carafa's contemporary, Mattheo Palmieri (1405-75), wrote a treatise entitled *Della vita civile* published in 1529 (posthumously) that is much more definite as to matters of taxation (especially in developing the doctrine that taxes are paid in con-

Nevertheless his performance holds a prominent place in the history of economic analysis. His systematic arrangement alone would suffice to show this. The first part of his book discusses the principles of general policy and of defense—compare A. Smith's lectures on arms—the second the administration of justice. The third is a little treatise on public finance and within measurable, though of course long, distance from the Fifth Book of the *Wealth of Nations*, 'Of the Revenue of the Sovereign or Commonwealth.' The fourth and last part presents Carafa's views on economic policy proper, and many an eighteenth-century treatise reads like an expansion of these views. There is no evidence that later writers took his book as a model and that, in this sense, he created the systematic form in which an important part of the work of the Consultant Administrators was to be cast. But as a matter of fact, he was, so far as I know, the first to deal comprehensively with the economic problems of the nascent modern state, and during the next three centuries a host of writers, adopting the same systematic ideas and defining their field similarly, followed in his wake and wrote in the spirit that he represented at its best. They no doubt learned to plough more deeply as well as to take new land under the plough. But they did not alter the general layout. In particular they not only adhered to, but in time also developed, the fundamental idea that Carafa clothed in his conception of the Good Prince (and which Sir James Steuart was to personify in his Statesman). This anthropomorphic entity is the embryo of their concept of a National Economy (in German, *Volkswirtschaft* or *Staatswirtschaft*), which reflects so well the historic process we have tried to visualize in the first section of this chapter. This National Economy is not simply the sum total of the individual households and firms or of the groups and classes within the borders of a state. It is conceived as a sort of sublimated business unit, something that has a distinct

---

sideration of the help and protection extended by the state to individuals in their economic activities, from which he deduced the principle of proportionality) but seemed to me, on the whole, to be inferior to Carafa's as a representative performance.

existence and distinct interests of its own and needs to be managed like a big farm. This was the way in which that epoch conceptualized the key position that governments and bureaucracies actually acquired, and also the way in which a distinction was drawn between political and business economy that survived to our own day, although, from a purely analytic standpoint, there is little to be said for it.

[(b) *Representative Performances: Bodin and Botero.*] In the sixteenth century this type of economics flourished in all continental countries. As representative performances—that were also outstanding in their influence on contemporary and later writers—we shall choose two works by Bodin and by Botero.[4] Both works are primarily treatises on 'political science'—written in the spirit of Aristotle's *Politics*—and as such are important stepping stones between Machiavelli and Montesquieu. Their economics is, like Carafa's, the economics of public policy and administration, taking its place beside all other branches of political knowledge. The economic analysis in the Sixth Book of Bodin's *République* is, however, hardly above the ideas that were current in its time and indeed does not go far beyond Carafa's, though his principles of taxation do mark further progress toward the Fifth Book of the *Wealth of Nations*.[5] Botero, who in some other respects may be classed as a follower of Bodin, made a much more important contribution to economic analysis that will be noticed in a subsequent chapter on population. Here, another remark suggests itself. Botero's treatise, especially if considered in connection with his other works, displays remarkable fact-mindedness. He was an able analyst. But the bulk of his labors went toward the collection, co-ordination, and interpretation of past and contemporaneous fact—economic, social, political. In this he was no exception. We have seen that the scholastic doctors of the sixteenth century were eager fact hunters and that they reasoned much more from observation and much less from abstract premisses than one might suppose. This was, however, still more the case with the literature now under discussion, whose greater part as well as main value may be said to consist in 'factual' investigations: then *as always, throughout the history of economics,* fact-finding was the chief care of the overwhelming majority of economists. Besides Botero's theory of population, Italy produced during the sixteenth century several other works that are much more important than the systematic literature we are now surveying, especially in the field of money (Davanzati, Scaruffi, see below, ch. 6).

---

[4] Jean Bodin or Baudin (Bodinus, 1530-96), *Les six livres de la République* (1576; 2nd ed. 1577; the one used, 1580). On the author and his works, see Henri Baudrillart, *Jean Bodin et son temps* (1853), a book which the lapse of nearly a century has not deprived of its authoritative position. This is the only one of Bodin's works that need be mentioned here; the other that is relevant to our subject will be noticed later (ch. 6). Lest the reader find that our text fails to do justice to the author, I want to emphasize that we consider only his contribution to economic analysis, which I believe to have been but modest, and not his much greater importance in other fields, the theory of sovereignty in particular.

Giovanni Botero (1544-1617), *Della ragion di stato* (1589, many editions and translations; recent ed. with introduction by C. Morandi, 1930, in the series *Classici del Pensiero Politico*). In order to appreciate the full significance of the work of this great man, two other publications must be mentioned: first, his *Delle cause della grandezza delle città* (1588), suggestive, in some points, of Montesquieu's *Grandeur des Romains* and also of Book III of the *Wealth of Nations*; and second his universal reports (*Relazioni universali*), compiled on his travels, on the power and resources of the states of Europe and Asia, which were published 1591-6.

[5] They would, I think, have to be Exhibit A in any proof of the continental, mainly French, origins of A. Smith's ideas on public finance.

[(c) *Spain and England.*] The very high level of Spanish sixteenth-century economics [6] was due chiefly to the scholastic contributions. But we may note what I believe to have been an early 'quasi-system,' the work of Ortiz,[7] mainly a well-reasoned program for industrial development of a type that was to be so prolific in the seventeenth century, both in Spain and in England. For Germany there is little to record. Two quasi-systems that seem to have met with success are, however, mentioned in the footnote below.[8]

At first sight one might conceive the impression that in sixteenth-century England there was little to correspond to the type of work surveyed so far. But this is not so. Corresponding work there was, only it took other forms owing to the different political structure of the people to which it was addressed. Discussion of the economic problems of the day, encouraged and also disciplined by the ritual of parliamentary and government inquiries, greatly improved throughout that century and occasionally rose to 'scientific' significance. From evidence given before royal commissions—such as the Royal Commission on Exchange, 1564—speeches, petitions, pamphlets on enclosures, guilds, companies, the staple system, monopolies, taxation, currency, customs, poor relief, wages, regulation of industry, and so on, a manual of economic analysis and policy might be compiled that would compare favorably with contemporaneous systematic efforts on the Continent.[9] Instead of attempting to do this we shall, however, follow a much easier course that is fortunately open to us. There are a number of publications that may be considered as general surveys of the economics of the time. In part, at least, they supply what we need. We shall confine ourselves to the most widely known of these treatises.[10]

---

[6] See E. Castelot, 'Coup d'oeil sur la littérature économique de l'Espagne au XVIe et au XVIIe siècle' (*Journal des economistes*, vol. 45, 1901); Manuel Colmeiro, *Historia de la economia politica en España* (1863) and *Biblioteca de los economistas españoles* (1880); another anthology is helpful, Juan Sempere y Guarinos' *Biblioteca española economico-politica* (1801-21), the Spanish counterpart of the Italian Custodi collection; A. V. Castillo, *Spanish Mercantilism* (1930); E. Hamilton, 'Spanish Mercantilism before 1700' (*Facts and Factors in Economic History* by former students of E. F. Gay); and José Larraz López, 'La Época del Mercantilismo en Castilla, 1500-1700' (Real Academia de Ciencias Morales y Politicas, 1943), and the review of this address in the *Economic History Review*, 1944, by J. Márquez. Señor Larraz speaks of a Spanish school—the 'school of Salamanca'—of sixteenth-century economists. There is indeed some justification for this. But the core of this school was made up of late scholastics, many of the most eminent of whom happened to be Spaniards; and there was nothing specifically Spanish about their teaching; the rest of Spanish sixteenth-century economists, though most of them were also clerics, do not form a school.

[7] Luiz Ortiz, *Memorial al Rey para que no salgan dineros de estos reinos de España* (1558; see Colmeiro's *Biblioteca*). Never mind the title, which might bring the work under ban on the score of 'mercantilism.' It has little to do with the true import of the argument and was presumably chosen by the author in order to attract the attention of laymen.

[8] Melchior von Osse's (c. 1506-57) *Politisches Testament*, written 1556, though published under the title *De prudentia regnativa* (1607), was reprinted by Thomasius for classroom use, as late as 1717. Georg Obrecht's (1547-1612) tracts on economic subjects (he is of more importance as a jurist) were posthumously published in 1617 as *Fünff underschiedliche Secreta Politica*. Bodin's influence is much in evidence.

The *Discourse of the Common Weal* contains three dialogues that deal with a wide variety of topics. The author regrets 'that younge studentes be alwayes over hastye in utterynge theire Jugementes,' and the 'seysme in matter of relygyen'; recommends better training all round, going so far as to consider superiority in 'lernynge' as one of the reasons for Julius Caesar's victory over Pompey; condemns enclosures in so far as they turn arable land into pasture; criticizes the rising business corporations and their monopolistic practices; disapproves of debased currency and of inflation that hurts people whose incomes do not react promptly, such as the laborers,[11] landlords, and even the King's Highness; recommends the fostering of young industries as well as the accumulation of a monetary fund for emergencies ('sodeyne eventes')—money being as it were a 'storehouse of any commodity' and *nervus bellorum;* does not favor the export of raw materials, especially of wool; frowns upon these 'straungers' who sell nothing but frivolous stuff that costs them little though the English pay dearly for it, and buy in return good honest English goods, if indeed they do buy anything and do not take 'monye currant' outright, which they prefer to do of late; feels that foreign commodities should be taxed so that domestic producers *might be able to compete;* wants to see the nation's money kept in the country and to recover that which has already left it. And so on.

---

[9] The best way for the reader to satisfy himself of this quickly is to glance through the source book already mentioned, Bland, Brown, and Tawney, *English Economic History: Select Documents* (1914), and through the still more useful compilation, Tawney and Power, *Tudor Economic Documents*, being select documents illustrating the economic and social history of Tudor England (3 vols., 1924), the third volume of which contains 'pamphlets, memoranda, and literary extracts.'

[10] This is a book entitled *A Compendious or briefe examination of certayne ordinary complaints, of divers of our countrymen in these our days: which although they are in some part iniust & frivolous, yet are they all by way of dialogues throughly debated & discussed*. To Miss Elizabeth Lamond we owe an excellent critical edition under the title *A Discourse of the Common Weal of this Realm of England* (1893), which besides the text presents the results of careful researches into the nature and the origin of the work. She attributed it to John Hales, a public official who also served in parliament and on the commission on enclosures of 1548, and assumed that it was written in 1549. Both statements have been questioned. But for us it is more important to note that the edition printed in 1581, and from which were made all the later editions (1751, 1808, 1813, 1876), differs from an earlier one (1565), the most important difference being the addition of a passage on the causes of the rise in general prices: whereas the edition of 1565 speaks only of the deterioration of the coinage, the later one also mentions the increase in the supply of the precious metals. Whoever made this addition therefore *may* be entitled to a share in such credit as this 'discovery' deserves, though Bodin's priority (*Response aux paradoxes de Monsieur de Malestroit*, 1568; see below, ch. 6), not only as to publication but also as to the discovery itself, is of course established beyond doubt by the existence of the volume of 1565. On the works of Clement Armstrong or Armeston that would have served our purpose equally well, see S. T. Bindoff's paper in the *Economic History Review*, 1944.

From these indications, the reader should be able to draw a picture of our author's economics. Of course, it was popular—preanalytic—economics. But most of it was sound common sense. The 'doctor' of the dialogues was evidently a thoroughly reasonable man and never said anything that would seem absurd to the intelligent layman or politician of today. In one respect, however, he was especially reasonable for his time. He distrusted regulation less than did the liberals of the nineteenth century but more than we do ourselves. He did not like compulsion. He wished to work with and not against the profit motive, which he considered quite essential. Moreover, he sometimes saw below the surface of things. For instance, he saw quite correctly that the encroachment of sheep runs upon the arable land had much to do with the policy that aimed at keeping wheat cheap by means of price fixing and export prohibitions, and thus defeated its purpose by altering the relative profitability of wheat and wool production in favor of the latter. This piece of reasoning (analoga of which are frequently met with in the writings of the Consultant Administrators) goes beyond the obvious. In its implications, it approaches the status of analytic work.

4. The Systems, 1600-1776

[(a) *Representatives of the Earlier Stages.*] The richer developments of the seventeenth and eighteenth centuries are much more difficult to convey. Keeping in mind our plan of campaign we shall, in this section, provisionally disregard everything else and go through with our survey of the 'systematic' literature of those two centuries until we reach the neighborhood of the *Wealth of Nations.* The earlier stages of this type of work will be represented by Montchrétien for France, by Bornitz and Besold for Germany, and by Fernández Navarrete for Spain.

Antoyne Montchrétien, Sieur de Watteville (c. 1575-1621), *Traicté de l'oeconomie politique* (1615), seems to have been the first to publish a book under the title of

---

[11] The Elizabethan Statute of Apprenticeship, 1562/3 (5 Eliz. c. 4), introduced, however, what we should call index wages: that is to say, wage rates were to be adjusted annually according to the changes in the cost of living.

Political Economy. This was, however, his only merit. The book is a mediocre performance and completely lacking in originality. Though there is a rough common sense about its recommendations, it abounds in elementary slips of reasoning that indicate a level of competence rather below than above its own time. For a thoroughly different appraisal, see T. Funck-Brentano's introduction to his edition of the work (1889), and also P. Lavalley's study, *L'Oeuvre économique de Antoine de Montchrétien* (1903).

Jacob Bornitz, *Tractatus politicus de rerum sufficientia in republica et civitate procuranda* (1625), an ill-digested compilation of economic facts; Christoph Besold's (1577-1638) *Collegium politicum* (1614), *Politicorum libri duo* (1618), and, to mention another of his numerous works, *Synopsis politicae doctrinae* (1623), moved on the higher level of the polyhistoric learning of this famous teacher, though he was inferior to Bornitz in factual knowledge; his treatment of interest anticipated that of Salmasius; Bodin's influence is unmistakable.

Pedro Fernández Navarrete, *Discursos* (first 1621; later edition under the title *Conservación de monarquias*, 1626). This author, an officer of the Inquisition, displays a remarkable freedom from the tendency of his (and our own) time to overstress the importance of the monetary factor and a not less remarkably sound judgment in maintaining that a normal process of industrialization would have gone far toward remedying the ills from which Spain was suffering (the value added to raw materials by human labor being much more important than gold and silver, see the sixteenth of his fifty *Discursos*) and that this process was capable of being accelerated by removing obstacles. I feel fairly confident that I am right in preferring Fernández Navarrete's performance to that of the equally well known Moncada (*Discursos*, 1619, republished as late as 1746 under the title *Restauración politica de España*) so far as ability to analyze is concerned.

Four further names will suffice to characterize what may be considered a more advanced stage: Martinez de la Mata, who developed a program of industrial policy on the lines of Fernández Navarrete; Seckendorff, who wrote the first outstanding treatise on the public administration and policy of German principalities; the great name of Sully, whom we neglect as we must; and Du Refuge (Philippe de Béthune), who went much beyond either Bodin or Montchrétien.

Francisco Martinez de la Mata is known for his *Memorial ó discursos en razón del remedio de la despoblación, pobreza y esterilidad de España* (1650; the *Epitome de los discursos* . . . 1701, is all I know; Sempere y Guarinos, op. cit. vol. III contains extracts). This work of the self-styled 'servant of the afflicted poor' (*siervo de los pobres afligidos*) must have been a great success. The fundamental soundness of its main thesis—the same as Navarrete's—is, in fact, beyond doubt and was to be repeated by a chorus of later economists.

Veit Ludwig von Seckendorff (1626-92), himself a distinguished administrator, published in 1656 the *Teutscher Fürstenstaat*, the classic work of its genus. Behind the descriptive and pedagogic program there is a definite social vision and a definite policy. The given end being a numerous and well-employed population, protection and internal freedom of industry and trade—which will of itself eliminate obsolete craft guilds—compulsory elementary education, and a system of taxation based upon the excise—which by bearing lightly on the higher incomes will increase employment—are the principal means envisaged. We shall presently see that this was, and continued to be, the typical program—and, by implication, the typical analysis of the German and Italian 'cameralists' throughout their careers, that is, up to the first decades of the nineteenth century. The man who first formulated it definitely and correctly, and in doing so anticipated, in some points, the developments of more than a century to come, was no second rater. On the contrary, he towers high, as a man and as an intellect, above many a writer who figures much more prominently in these pages. But explicit analysis, that is, conscious efforts to state relations of causation or interdependence, is hard to find in his work. And what there is of it, is not up to much.

Maximilien de Béthune (1560-1641), created Duke de Sully by Henry IV, the latter's minister of finance, was a much greater and especially stronger man than was the most famous of his successors, Colbert. He reformed the fiscal system of France most successfully and saw much beyond the range of what he actually accomplished. Moreover, he knew—which is the criterion of greatness in a fiscal administrator—how to make fiscal policy an element and tool of general economic policy. His *Économies royales* (first publ. 1638; a selection, which is all I know, has been republished in Guillaumin's *Petite bibliothèque économique*) are substantially memoirs of his administration and make, in their quaint form, charming and most instructive reading. But there is no point in calling him a forerunner of the physiocrats, on the strength of his preoccupation with the welfare of the agrarian population and of his saying that husbandry and pasture were the two *mamelles* of France. Nothing can be more obvious than that this man was entirely innocent of any theory whatever.

Eustache Du Refuge's * work, *Le Conseiller d'estat ou recueil général de la politique moderne* (1645), descends from that of Bodin. The first forty chapters deal with the various forms of government, tolerance, the duties of magistrates, conscription, and so on; Chapters 41 to 44 are to all intents and purposes a treatise on economics and economic policy in outline; the rest includes, among other things, public finance, especially taxation, and marks another step toward A. Smith's Fifth Book. Du Refuge's economics is remarkable in several respects. In particular he was the first author I know of to distinguish and at the same time to co-ordinate the effects of 'parsimonie' (ch. 44) which conserves wealth and of *l'espargne* (hoarding, ch. 49) which interferes with commerce. In this and in other points he made a creditable effort to analyze.

Throughout the rest of the seventeenth and practically the whole of the eighteenth century the same type of work was turned out by an increasing number of writers, among whom academic teachers rapidly gained the majority. In some countries, especially in Germany, it was the main domestic source of economic teaching even in the first decades of the nineteenth century. Much of it was, however, so distressingly unoriginal and so obviously written in response to demand rather than to creative impulse that there would be no point in following its history in any detail. For our purposes, that is to say, in order to get an idea of its general character and to see how far it had advanced at the threshold of the Smithian age, it will suffice to introduce two eighteenth-century authors of international reputation, Uztáriz and Justi, and to take up for discussion one of the works of the latter.

---

* [This work, *Le Conseiller* . . . (published anonymously), was attributed to Du Refuge when J. A. S. used it in the Kress Library; recently it has been attributed to Phillipe de Béthune, Comte de Selles de Charost. There is an English translation as early as 1634 which implies an earlier date for the original French publication.]

Gerónimo Uztáriz (1670-1732) wrote a treatise entitled *Theórica y práctica de comercio y de marina* (1st ed. 1724, two other editions improved by the author himself), which may be said to be related to Martinez de la Mata's as the latter's treatise is to Fernández Navarrete's. It was translated into English and French and widely read and admired. The title is misleading in two respects. First, it suggests limitation to topics of international trade, whereas it deals comprehensively with practically all the problems of taxation, monopoly, population, and so on that come within the range of 'applied' economics. Second, the title also suggests theoretical analysis, though none is to be found in the treatise: what he, like so many later economists, means by theory is criticism and recommendation as distinguished from the presentation of facts. The care and space bestowed on the latter (he reprinted or extracted so many documents as to make his treatise serve the purposes of a source book) is what strikes the reader first. The recommendations acquire for us additional historical interest when we remember that Uztáriz held public office of the policy-making kind at the time when Cardinal Alberoni was at the head of affairs: the latter followed—not without considerable success—exactly the policy of armament and industrialization that Uztáriz recommended in the treatise which appeared five years after the Cardinal's fall. Whatever this fact may mean—the reader's guess is as good as mine—our author must certainly be commended, considering the then situation of his country and the standpoint from which he viewed it, for the correctness of such analysis as may have been behind his recommendation.

[(b) *Justi: the Welfare State.*] Johann Heinrich Gottlob von Justi (1717-71) was a professor for part of his life and an administrator of public enterprises for another part. His intellectual equipment covered all the natural-law philosophy of his and the preceding epoch but was enriched by practical experience in a way in which the two were rarely combined. Of course, we must grant the professor a fair ration of ponderous triviality, and also allow for his way of arriving at common-sense conclusions by a circuitous route that leads through questionable political philosophies. An example will illustrate the latter point: freedom is absolute by virtue of natural law; only, as the professor has somewhere learnedly shown, it consists in freedom to obey the laws and the rulings of the bureaucracy; but the latter as taught by Justi is so very reasonable that after all we come out of the woods with the result to be presented in the text. Of Justi's numerous works his *System des Finanzwesens* (System of Public Finance, 1766) has been chosen by Professor Monroe for partial publication in *Early Economic Thought* (1924). Our sketch in the text is based upon *Die Grundfeste zu der Macht und Glückseeligkeit der Staaten oder ausführliche Vorstellung der gesamten Polizeywissenschaft* (The Groundwork of the Power and Welfare of States or Comprehensive Presentation of the Science of Public Policy, 2 vols., 1760-61). We are concerned with the first volume only. The second contains, in the spirit of that science of administration, dissertations on religion, science, the government of the private household, civic virtues, fire brigades, insurance—of which Justi was a fervent advocate—regulation of dress, and the like. His *Staatswirtschaft* (1755) would have served equally well.

Instead of Justi, I might have chosen Joseph von Sonnenfels (1732-1817; *Grundsätze der Polizey, Handlung, und Finanzwissenschaft*, 1765-7), who was in several respects superior to Justi, though in substance he moved on the latter's and Forbonnais' lines. The son of a Berlin rabbi, he became, after emigrating to Vienna, one of the lights of that 'age of reason' and took part, both as an academic teacher (being the first professor of policy and cameral science in Vienna) and as a civil servant in many of the legislative reforms of his time: he was a member of what may be described as Joseph II's brain trust. His book remained the official textbook within the Austro-Hungarian monarchy until 1848. The subject of his inaugural lecture (1763) deserves to be noticed. It was on the Inadequacy of Mere Experience in Economics.

The subject of Justi's inquiry is what German historians call the Welfare State (*Wohlfahrtsstaat*) in its historic individuality and in all its aspects. That is to say, he dealt with economic problems from the standpoint of a government that accepts responsibility for the moral and economic conditions of life—just as modern governments do—in particular for everyone's employment and livelihood, for the improvement of the methods and organization of production, for a sufficient supply of raw materials and foodstuffs, and so on through a long list of topics that include beautification of cities, fire insurance, education, sanitation, and what not. Agriculture, manufactures, commerce, money, banking—all come in for discussion from this point of view, technological and organizational aspects receiving much attention. But having thus pinned his faith to a principle of comprehensive public planning, he, like Seckendorff and most of the writers between these two, did not arrive at the practical conclusions this principle might lead us to expect. On the contrary, he was by no means blind to the inherent logic of economic phenomena, and did not wish to replace it by government fiat. Price fixing, for instance, was a measure to which the government had the right and duty to resort for particular purposes in particular circumstances, but it was to be avoided as much as possible. He took Mirabeau to task for teaching, among other 'false, nonsensical, and monstrous doctrines,' that the lowering of interest depends upon the will of government whereas actually 'nothing is so little subject to it.' Nor was he blind to the potentialities of free enterprise, on which he looked with detachment but without hostility. In fact, notwithstanding his approval of government regulation, which goes so far as to make him admit the expediency of enforcing the production of certain things by government decree, he stated as a general principle that all industry and commerce really needed was freedom and security. Though he would not advise the liquidation of artisans' guilds—because they were there and might just as well be used for filling some administrative functions he considered useful —he nevertheless looked upon them as a nuisance and advised governments not to be hard on outsiders. And, though he taught that high protective duties and even import prohibitions and compulsion to buy domestic products might 'sometimes' be in the public interest, he nevertheless declared it to be his opinion that 'in general' there should be no impediment to imports beyond an ad valorem duty of 10 per cent—a condition which none of us would be able to distinguish from unrestricted free trade.

Many other instances could be adduced for what to nineteenth-century liberals simply spelled discreditable inconsistency, which they were inclined to attribute to the fact that Justi lived in a transitional age: while still a victim of exploded error, he could not quite shut his eyes to the new light. But if we look more closely at the particular cases to which he applied his principle of planning, a very different explanation suggests itself. He saw the practical argument for laissez faire not less clearly than did A. Smith, and his bureaucracy, while guiding and helping where necessary, was always ready to efface itself when no guidance or help seemed needed.[1] Only he saw much more clearly than did the latter all the obstacles that stood in the way of its working according to design. Also, he was much more concerned than A. Smith with the practical problems of government action in the short-run vicissitudes of his time and country, and with particular difficulties in which private initiative fails or would have failed under the conditions of the German industry of his time. His laissez-faire was a laissez-faire plus watchfulness, his private-enterprise economy a machine that was logically automatic but exposed to breakdowns and hitches which his government was to stand ready to mend. For instance, he accepted as a matter of course that the introduction of labor-saving machinery would cause unemployment: but this was no argument against the mechanization of production because, also as a matter of course, *his* government would find equally good employment for the unemployed. This, however, is not inconsistency but sense. And, to us who are apt to agree with him much more than we do with A. Smith, his vision of economic policy might look like laissez-faire with the nonsense left out.[2] But two Spanish examples show still better than does Justi's how well the best brains of that time knew their 'applied economics': I am referring to Campomanes and Jovellanos,[3] who rose to prominence in the reform era of Charles III. They were practical reformers in the line of economic liberalism, and neither bothered about nor contributed to the progress of analysis. But they understood the economic process better than did many a theorist. And, in view of the date of Campomanes' *Discurso* (1774) it is not without interest to observe how little, if anything, he stood to learn from the *Wealth of Nations*.

---

[1] This was not merely a dream. It will be pointed out below that the bureaucracy of the typical German principality actually tried to behave like this.

[2] Such views, which were extremely common at the time, naturally assumed an anti-Smithian garb that exaggerates the difference. This was the case, e.g., with Justus von Möser (*Patriotische Phantasien*, 1774-86), whose name I also mention for another reason. His interest in the description of individual historical patterns—a sort of historical miniature painting—has induced some historians of thought to assign to him the position of early romanticist or forerunner of the historical school: an example of those unrealistic attributions that, once made, keep on distorting our views of groups and developments. He was an excellent man, no doubt, but he was no economist at all.

[3] Pedro Rodriguez, Count Campomanes (1723-1802) was by training a jurist economist of the continental type. A man of wide culture and great ability, he tried his

This covers, and indeed sums up, a large part of continental seventeenth- and eighteenth-century economics. The reader should realize, however, that though in practical insight and practical usefulness, it was—at least as it came to be taught eventually—hardly inferior to the *Wealth of Nations*, it also was, with the exception to be noticed presently, completely outdistanced by the latter as regards analytic achievement. Justi's work exemplifies this weakness as clearly as it exemplifies those merits. I have said that he was not blind to the inherent logic of economic phenomena. But this was mere prescientific intuition. He did nothing to show how they hang together and how they determine each other, which is where scientific economics begins. He was not alive to the necessity of proving propositions—for instance, his proposition that mechanization creates unemployment—or of using any tools not at the layman's command. His arguments were the arguments of untutored common sense; it was only when he argued against another author that he attempted any analysis at all. And when he did so, he occasionally slipped up badly. To quote an instance, he was not above pulling the following atrocious boner: suppose that two countries, *A* and *B*, are exactly alike in every respect except that *A* holds twice as much monetary silver as *B*; while their states of welfare will be exactly equal, prices in *A* will be twice as high as prices in *B*; but owing to the double quantity of money, *A*'s rate of interest will be half of *B*'s rate of interest and therefore *A*, producing more cheaply, will undersell *B* and keep on drawing money from it, which will increase employment in *A*, and so on (*Die Grundfeste*, p. 611)—and all that in spite of the facts that his reasoning on interest was otherwise quite sensible, that in general he did not at all overrate the advantages that accrue to a country from an abundance of metals, and that he emphasized the basic importance of consumption not less than did A. Smith.

---

hand, both in office and out of it, on all the great economic problems of his time and country. Of his writings, the one most relevant to our purpose is his *Discurso sobre el fomento de la industria popular* (1774), which was to move McCulloch to fervent eulogy. The *Respuesta fiscal* (1764), concerning the grain trade, should also be mentioned.

Gaspar Melchor de Jovellanos (1744-1811), a man of similar type but of a less prosperous career, among many other things wrote two reports, one on the liberty of the industrial arts (1785), and another, on behalf of the Royal Economic Society of Madrid, on agrarian legislation (1794), in both of which the principles of economic liberalism are expounded, but judiciously tempered by practical considerations. They were published (1859) in the *Biblioteca de Autores Españoles*. However, their dates reduce their importance, as compared with Campomanes' tracts, for the historian of economic thought.

[(c) *France and England.*] The French civil servant was educated as an abbé or else as a lawyer. Economics was not taught, as a distinct subject, until during and after the revolution. Could it be that this great disadvantage carried some compensation? In any case, the much less voluminous French literature of the systematic type rose in the eighteenth century to a level far and away above the German. Since we reserve such peaks as Boisguillebert, Cantillon, Turgot, and, of course, the physiocrats for discussion in the next chapter, we may content ourselves with the five following names—Forbonnais, Melon, Mirabeau, Graslin, and Condillac. Forbonnais,[4] who might be compared with Justi or Sonnenfels, is the prototype of the 'useful' or 'sound' economist of whom the public approves. No historian will ever sing his praises; for the historian who is interested only in what policy a man was for or against will not be satisfied and will put down Forbonnais as an eclectic without originality; and the historian who looks for contributions to our analytic apparatus will also be dissatisfied, for he will not find it, and he will notice clumsy and pedestrian behavior whenever Forbonnais did venture upon theoretical ice. But few economists ever said or implied so little that is definitely and provably wrong in either fact or logic. He is an outstanding example by which to illustrate the truth that to be an economist or physician is one thing and that to be a theorist or physiologist is quite another thing.

Markedly inferior to Forbonnais in these respects and but little above him in analytic proficiency, Melon [5] has fared somewhat better at the hands of later critics. But his performance, which, so far as 'principles' are concerned, partly anticipated Forbonnais', is of much the same nature. His contribution to monetary theory will be noticed in a subsequent chapter. The elder Mirabeau[6] is primarily known as the head, in succession to Quesnay, of the physiocrat group, but he had independently established himself before that by a work that may be called a systematic treatise on all the problems of applied economics written from a very personal standpoint—systematic unity being achieved by making those problems pivot on Population and Agriculture. Its analytic merit is negligible, but all the greater was its success. Graslin's[7] reputation never was what it should have been because he put so much emphasis upon criticism of the physiocrats—which is in fact the best ever proffered—that his readers were apt to overlook his positive contribution. Actually, his *Essai analytique* presents the outlines of a comprehensive theory of wealth as a theory of total income rather than of income net of all producers' expenses including wages—a not inconsiderable improvement considering the role the latter was to play later on. Also he was above his contemporaries in insight into the problem of incidence of taxation. Finally, Condillac's work[8] does not indeed quite merit the eulogies of W. S. Jevons, who called it 'original and profound' and of H. D. Macleod, who called it 'infinitely superior to A. Smith's.' The eulogies are amply accounted for by the enthusiasm of those two authors for what they believed to be an early formulation of their own theory of value. But there was nothing original about it and, considering all the predecessors on that path, we should wonder at Condillac's inefficient handling of it rather than at his sponsorship of it. Still, the book is a good if somewhat sketchy treatise on Economic Theory and Policy and much above the common run of its contemporaries.

---

[4] François Véron de Forbonnais (1722-1800) was a businessman and civil servant and, being a Frenchman, addressed a different public and envisaged different conditions, so that the similarity between his and Justi's performances does not stand out at first sight. Fundamentally, however, he did—very successfully—the same kind of thing. His practical grasp of the social and economic situation confronting him was his, as it was Justi's, chief merit. He is at his best in his analyses of definite sets of historic facts such as the finances of France from 1595 to 1721 (1758) or the finances of Spain (1753). For us the most interesting of his works are: *Élémens du commerce* (1754 and 1766) and *Principes et observations économiques* (1767; the latter is available in the Guillaumin collection, reading recommended: not below the average nineteenth century textbook and superior to a good many). His recommendation of an ad valorem import duty of 15 per cent may be mentioned as one of several instances of parallelism between his views and those of Justi, whom the first volume of his *Élémens* may have influenced. That he influenced Sonnenfels as much as did Justi is obvious from acknowledgments.

[5] Jean François Melon (1675-1738) was a public servant who worked with John Law during the short career of the latter's 'system' and thus had first hand knowledge of it. His *Essai politique sur le commerce* (1734, English trans. 1738) was a great success in France and abroad and exerted considerable influence. The misleading term Neo-Mercantilism is sometimes used to designate the views on foreign trade and finance that he and other eighteenth-century writers espoused (see below, ch. 7). See G. Dionnet's *Le Néomercantilisme au XVIII^{e} siècle et au début du XIX^{e} siècle* (1901) and also L. de Lavergne's *Les Économistes français du dix-huitième siècle* (1870).

---

[6] Victor Riquetti, Marquis de Mirabeau (1715-89), called the elder to distinguish him from his son, the Mirabeau of the Revolution, was an eccentric aristocrat of exuberant vitality and irrepressible impulses. It is difficult to understand—except on the hypothesis that force of temperament and glowing phrases will always carry everything before them—how it was that this man, whose unquestioned ability was completely spoiled by lack of judgment, could have enjoyed, though only for a few years, an international and national fame much greater than that of any other economist before or after, not excluding A. Smith or K. Marx. This happened in the first part of his career, that is, before he had joined the physiocrats, and on the strength of a performance that cannot be called impressive in anything except passionate phraseology. This performance, anonymously published in three parts under the title *L'Ami des hommes, ou traité de la population* (1756), will have to be mentioned again in our chapter on population. Of all the other works of Mirabeau—he left dozens of volumes besides a quantity of unpublished material—only the subsequent parts (4-6) of *L'Ami* (1758 and 1760), the *Philosophie rurale* (1763), and the *Théorie de l'impôt* (1760) call for notice in this book. The last two are, however, physiocratic, at least in principle, and therefore need not detain us here. See L. and C. de Loménie, *Les Mirabeau* (1879-91) and L. Brocard, *Les Doctrines économiques et sociales du Marquis de Mirabeau dans L'Ami des hommes* (1902).

[7] Jean J. L. Graslin (1727-90), *Essai analytique sur la richesse et sur l'impôt* (1767; new ed. by A. Dubois, 1911). See J. Desmars, *Un précurseur d'A. Smith en France, J. J. L. Graslin* (1900). His correspondence with Baudeau is of considerable interest (2 vols., 1777-9).

[8] *Le Commerce et le gouvernement* . . . (1776) by the sensationalist philosopher and psychologist we have already met above. The relation between his psychology and his utility theory of value should not be overstressed. As we know already and as we shall see more fully later on, the latter has a quite independent history of its own that harks back to the scholastics rather than to Hartley. Condillac's relation to the physiocrats should not be overstressed either. Rather he had learned from Turgot. See, however, A. Lebeau, *Condillac économiste* (1903).

England was still more immune to 'systemitis' than was France. Excepting the *Wealth* itself, there is but one book of the strictly systematic type to mention, but this one is of first-rate importance, Steuart's *Principles*.[9] It was intentionally and laboriously systematic: what he wanted was to consolidate the factual and analytic knowledge of his time into a 'regular science,' that is to say, he clearly aimed at the same goal as A. Smith. Comparison with the *Wealth of Nations* is rendered difficult by two facts. In the first place, Steuart's work did not ride, like Smith's, on the wave of a single and simple policy that was rapidly conquering public opinion. On the contrary, he grouped all that really interests the public around the old-fashioned figure of an imaginary patriot statesman who in infinite wisdom watches the economic process, ready to interfere in the national interest—a conception that recalls Justi's and was quite out of contact with England's humor. But this should not weigh with us. In the second place, when one surveys (as the reader should) the five books into which the work is divided—Population, Trade and Industry, Money and Coins, Credit and Debts, and Taxes—one cannot fail to be struck by the number of points that indicate more originality and deeper thought than does the *Wealth of Nations;* but also by the number of definite mistakes and infelicitous formulations. In the theories of population, prices, money, and taxation Steuart went much below the smooth surface on which A. Smith happily sailed his course. But only in the first of these did he make a significant contribution, which will be discussed below in Chapter 5; in the others it is a hard job to get the wheat out of unpromising chaff or even, in some instances, to be quite sure that there is any wheat at all.

[(d) *High Level of the Italian Contribution.*] But the honors of the field of pre-Smithian system production should go to the eighteenth-century Italians. In intent, scope, and plan their works were in the tradition that has been illustrated by the examples of Carafa and Justi; they were systems of Political Economy in the sense of welfare economics—the old scholastic Public Good and the specifically utilitarian Happiness meeting in their concept of welfare (*felicità pubblica*). But whereas in zeal for fact-finding and in grasp of practical problems they were not inferior to the Germans, they were superior to most of their Spanish, English, and French contemporaries in analytic power and achievement. Most of them were professors and civil servants and wrote from the standpoint of professors and civil servants. The regionalism of Italian life[10] divides them into groups. But I can discern only two 'schools' in the strict sense of the term which implies both personal contact and similarity of doctrine due to mutual influence: the Neapolitan and the Milanese. Genovesi and Palmieri represent the former;[11] other members, particularly its brightest star, Galiani, will be introduced later.

---

[9] Sir James Steuart (1712-80), the scion of a family that held a prominent position in the Scottish magistracy, was educated as a lawyer, and, being an adherent of the Stuarts, lived in exile from 1745 to 1763—three facts that go some way toward explaining both the nature and the reception of his performance; on the one hand, there is something un-English (which is not merely Scottish) about his views and his mode of presentation, the latter being stiff and embarrassed in the bargain; on the other hand, he was, and even after he had regained the rights of citizenship remained, distinctly under a cloud. Such things count. In particular, they make it easy for competitors to pass a man by in silence, which is precisely what A. Smith did. *An Inquiry into the Principles of Political Economy* . . . 1767, accordingly was never much of a success in England even before it was completely overshadowed by the *Wealth of Nations.* But it received rather more than its due from some of the Germans. Other writings by Steuart will be mentioned later. His collected *Works* were edited by his son (1805).

The representative figures of the Milanese school are Verri and Beccaria. We take, however, this opportunity to introduce a man who stands quite by himself, Ortes the Venetian.

---

[10] This regionalism accounts for the existence of Italian histories of 'provincial' economics, a phenomenon for which there is no analogy in any other country except Spain. Two examples may be mentioned: Augusto Graziani's *Le idee economiche degli scrittori Emiliani e Romagnoli sino al* 1848 (1893), and T. Fornari's *Delle teorie economiche nelle provincie Napoletane dal secolo XIII al MDCCXXXIV* (1882), the complement of which will be cited in the next footnote.

[11] Antonio Genovesi (1712-69), professor, first of ethics and moral philosophy, then of economics and commerce, in the University of Naples, was first and last a great teacher whose prodigious success in this capacity even his detractors have been unable to deny. It was I think F. Ferrara who set the example of speaking of Genovesi in derogatory terms, possibly because he never could see any merit in anyone who was not a thoroughgoing free-trader. For a list of prominent economists who were his pupils (see G. Tagliacozzo, *Economisti Napoletani* (p. xxvi n.). The same author, moreover, draws a picture of Genovesi's scientific personality and background (on these also see A. Cutolo, *Antonio Genovesi*, 1926) and gives a judicious appraisal of his performance. Genovesi was a prolific writer. We are concerned, however, only with his *Lezioni di economia civile* (1765; republ. in P. Custodi's *Scrittori classici Italiani di economia politica*, 50 vols., 1803-16), which may be described as an unsystematic system of the whole range of his economic thought. These lectures do indeed display the influence of contemporaneous and earlier writers and, what is worse, the argument frequently lacks rigor. But nobody had, when they appeared, published as comprehensive a presentation of the utilitarian welfare economics that the epoch was evolving. The 'mercantilist' elements in Genovesi's teaching only prove the realism of his vision.

Giuseppe Palmieri, Marchese di Martignano (1721-94?), was one of that brilliant band of Neapolitans in which Filangieri (see P. Gentile, *L'Opera di Gaetano Filangieri*, 1914) was perhaps the most widely known figure. Palmieri (there is a life by B. De Rinaldis, 1850; also see T. Fornari, *Delle teorie economiche nelle provincie Napoletane*, 1735-1830, 1888) was primarily a practical administrator. But the welfare economics of the eighteenth-century Consultant Administrators can perhaps be best appreciated by reading his *Riflessioni sulla pubblica felicità relativamente al regno di Napoli* (1787) or his *Pensieri economici* . . . (1789) or his *Della ricchezza nazionale* (1792).

Count Pietro Verri (1728-97), an officer in the Austrian administration of Milan—but not a teacher—would have to be included in any list of the greatest economists. But though it would be easy to survey his various recommendations as to policy—which for him were the important things; in the preface to his main work, he exclaimed: *potessi io dire qualche cosa di utile, potessi io farla* (how I wish to say something useful, nay, to do it!)—it is less easy to convey an idea of his purely scientific achievement; some aspects of it will be mentioned later. Here we need to mention only two of his many publications, the *Elementi del commercio* (1760), which established him, and the *Meditazioni sull' economia politica* (1771; republ. in the Custodi collection; there are French and German translations) into which the former was expanded. Besides presenting a powerful synthesis, these works contain a number of original contributions (among them his constant-outlay demand curve). Among other things, he had a clear if undeveloped conception of economic equilibrium based, in the last instance, upon the 'calculus of pleasure and pain' (he anticipated Jevons' phrase) and was, as far as this goes, rather above than below A. Smith. It is important to emphasize his fact-mindedness. Not only did he do historical research of importance (*Memorie storiche,* posthumously published) but he was a true econometrician—for example, he was one of the first economists to figure out a balance of payments—that is to say, he knew how to weave fact-finding and theory into a coherent tissue: the methodological problem that agitated later generations of economists he had successfully solved for himself. On the man and his career, see E. Bouvy, *Le Comte Pietro Verri* (1889), and M. R. Manfra, *Pietro Verri* . . . (1932). The best exposition and appraisal of Verri's work is, however, to be found in Professor Einaudi's masterly introduction to his new edition of Verri's *Bilanci del commercio dello stato di Milano* (1932).

Giammaria Ortes' (1713-90) main title to fame is in his contribution to the 'Malthusian' theory of population (see below, ch. 5). His systematic venture (*Economia nazionale,* 1774; republ. in the Custodi collection) will always stand out in the history of the theories that look upon consumption as the limiting factor of *total* output and derive from this set-up their economic diagnosis—this is another link between him and Malthus. In this as in some other respects his performance is certainly original in the sense that it does not lie on the main road of advance. But little else can be said for it. Critics and historians have been, on the one hand, puzzled by it and, on the other hand, reconciled by his attack on the 'mercantilist confusion' (see below, ch. 6) of money and wealth and his free-trade views. Thus, a tradition has developed of dealing with him in an attitude of diffident admiration. It is worth while adding that he seems to have learned much from Sir James Steuart. From the Ortes literature it will suffice to mention A. Faure, *Giammaria Ortes* . . . (1916), the old book by F. Lampertico, *G. Ortes* . . . (1865), and C. de Franchis, *G. Ortes, un sistema d'economia matematica* . . . (1930), though I cannot myself find much mathematics in Ortes.

Cesare Bonesana, Marchese di Beccaria (1738-94), was a Milanese and the product of Jesuit education. His international fame as a penologist, won at the age of about thirty (the year of his birth is not quite certain), and the place he incidentally acquired in the history of utilitarianism have been mentioned already. Mainly on the strength of this success—he had as yet done little as an economist—the Austrian Government (Prince Kaunitz) appointed him to a chair of economics in Milan founded for the purpose (1768). After only two years of tenure, he exchanged this chair for employment in the Milanese administration, in which he continued to serve until his early death, rising by degrees to the highest rank open to a man not qualifying for governor, taking part in, and in some instances initiating, the reforms of the period, busily writing a great many reports and memoranda—on grain storage, monetary policy, the metric system, population, and what not—and roaming over a wide realm of intellectual interests at the same time. Among other things, he was cofounder of, and a contributor to, *Il caffè*, a periodical modeled on the example of the English *Spectator*. In 1770 he published the first and only volume of his aesthetics (on *Style*). Moreover, he seems to have been a fair mathematician.

The bulk of his economic writings consisted of those government reports. The only piece of economic reasoning that he published himself (in *Il caffè*, 1764) was an essay on smuggling, which presents two features of interest, first, the algebraic treatment of the problem and, second, the analytic device embodied in the question he made basic to his pure theory of smuggling: given the proportion of the goods smuggled that will on the average be seized by the authorities, what is the total quantity that smugglers must move in order to be left without either gain or loss? This spells the discovery of the idea that underlies modern indifference-variety analysis. Beccaria's argument was developed by G. Silio, 1792 (see Augusto Montanari's *La matematica applicata all 'economia politica,* 1892). Here, we are concerned with Beccaria's lectures (written 1769-70). These he did not publish himself: he left them in his files for nearly a quarter of a century. They were first published in Custodi's collection, under the title: *Elementi di economia pubblica* (1804).

The sweeping success of his *Dei delitti e delle pene, An Essay on Crimes and Punishments* (1st ed. 1764; English trans. 1767) has in a way obliterated the greatness of the man: ever since he has been considered primarily as a penologist. The Beccaria literature deals with little else and is therefore only periphericallv interesting for us. Reference should be made, however, to P. Custodi's life (*Cesare Beccaria,* 1811) and to P. Villari's edition of his works (*Opere*, 1854).

For the moment, we concentrate upon Beccaria, the Italian A. Smith. The similarity between the two men and their performances is indeed striking. There is even some similarity in their social backgrounds and locations. There is similarity in their lives—and in those attitudes that are conditioned by one's pursuits—though Beccaria was much more of a public servant than A. Smith, who only held a subordinate position without creative possibilities, and A. Smith was much more of a professor than Beccaria, who taught for only two years. Both were sovereign lords of a vast intellectual realm that extended far beyond what, even then, was possible for ordinary mortals to embrace. Beccaria presumably knew more mathematics than A. Smith, but A. Smith seems to have known more astronomy and physics than Beccaria. Neither was merely an economist: A. Smith's life work contains no match for *Dei delitti e delle pene*, but his *Moral Sentiments* are more than a match for Beccaria's aesthetics. Both swam joyfully in the river of their time, but with a difference: whereas Beccaria not only accepted all utilitarianism stands for but also was a leading force in shaping it, A. Smith quite clearly showed some critical coolness toward it; and whereas A. Smith not only accepted (almost) all that free trade and laissez-faire stand for but also was a leading force in their victory (so far as economic literature is concerned), Beccaria clearly showed some critical coolness toward them. Splendid figures both of them. But, at least after 1770, Beccaria, almost certainly more richly endowed by nature, gave to the public service of the Milanese 'state' what A. Smith reserved for mankind.

Beccaria's *Elementi*, after defining the subject of economics in the same normative way as did A. Smith in the introduction to the Fourth Book of the *Wealth of Nations*, starts with considerations about the evolution of technology, division of labor, and population (the increase of which he made a function of the increase in the means of subsistence). As the principle of economic action, we know already, he embraced without qualification the utilitarian doctrine of hedonist egotism, which he himself had done much to develop, and which later on proved so embarrassing an ally to economics. The second and third parts of the lectures deal with agriculture and manufactures, and the fourth, on commerce, is made the repository of the theory of value and price: barter, money, competition, interest, foreign exchanges, banks, credit, and public credit follow each other in a sequence that is as suggestive of nineteenth-century textbook practice as is the framework as a whole. In detail, Beccaria's argument—particularly as to the theories of cost and of capital—is not always faultless or logically rigorous. But all the essential problems are seen, and seen in co-ordination. Some points will be mentioned in subsequent chapters. There are several contributions, however—such as the indeterminateness of isolated barter, the transition from this case to that of a determinate competitive market and thence to the case of indirect exchange—which we are in the habit of associating with much later, especially with post-Smithian, times. Physiocrat influence is in evidence but does not go very deep. Was the Scottish Beccaria the greater economist of the two? If we judge by their works as they lie before us, he certainly was. But to do so would not be fair to the men. It is not only that we must take into account priority and also that the years between 1770 and 1776 were very significant ones in the march of economic ideas; much more important is it that the *Wealth of Nations* was the mature result of a life's work whereas the *Elementi* are lecture notes and, moreover, lecture notes *which the author refused to publish.*

So far as subjective performance is concerned, they should not be matched with the *Wealth of Nations* but rather with the economic part of A. Smith's Glasgow lectures—where Beccaria would win hands down—or else the *Wealth of Nations* should be compared with what we might conceive Beccaria would have done with his lectures if he had emigrated to Kirkcaldy and spent another six years on them instead of immersing himself in the problems of the Milanese state. That the *main* cause of the difference we perceive consists in the amounts of labor invested is, in any case, an important clue to the secret of A. Smith's success.

[(c) *Adam Smith and the* Wealth of Nations.] [12] So often have we mentioned Adam Smith, so often shall we have to mention him again, that the reader might well wonder whether there is need for a comprehensive survey of his performance in any one place. For our purpose, the references to it that are scattered all over this history are in fact more important than what will be said in this section. Nevertheless, it seems proper to stay for a moment in order to look at the figure of the most famous of all economists—to form an idea of what stuff he was made—and at the most successful not only of all books on economics but, with the possible exception of Darwin's *Origin of Species*, of all scientific books that have appeared to this day. Moreover, it will again be useful to present a brief Reader's Guide.

Few facts and no details are needed about the man and his sheltered and uneventful life (1723-90).[13] It will suffice to note: first, that he was a Scotsman to the core, pure and unadulterated; second, that his immediate family background was the Scottish civil service—in order to understand his outlook on social life and economic activity (very different from what has been often imputed to him), it is important never to forget the gentility, the intellectuality, the critical attitude to business activity, the modest yet adequate means that characterized the environment which produced him; third, that he was a professor born and bred, not only while he lectured at Edinburgh (1748-51) and

---

[12] [There is no indication as to where this sketch of Adam Smith followed by a Reader's Guide to the *Wealth of Nations* belongs, but it seems appropriate to place it here at the end of the discussion of 'The Systems, 1600-1776.' This section was originally written for the *History* but was withdrawn by J. A. S., possibly at a time when he was attempting to reduce the length of the book or possibly because he felt that there was too much duplication in view of 'the references . . . that are scattered all over this *History*.' It is a first draft that was not even typed. Since, however, similar biographical sketches of other famous economists are presented throughout the book, it seemed appropriate to restore this account of Adam Smith and the *Wealth*. A reference to the Reader's Guide will be found below in ch. 6, sec. 3d (Codification of Value and Price Theory in the *Wealth of Nations*).]

[13] Of the many lives of Adam Smith the interested reader is referred to the one by John Rae (1895). Of all the books containing supplementary material on and interpretations of Smith the man, by far the most important is Professor W. R. Scott's *Adam Smith as Student and Professor* (1937), which will be referred to in the text and from which the reader will derive much instruction and, perhaps, some amusement. The minimum of references concerning the *Wealth* will be given later.

Glasgow (1751-63) but always and by virtue of *character indelebilis;* fourth—a fact which I cannot help considering relevant, not for his pure economics of course, but all the more for his understanding of human nature—that no woman, excepting his mother, ever played a role in his existence: in this as in other respects the glamours and passions of life were just literature to him. In 1764-6 he traveled in France, acting as 'tutor' to the young Duke of Buccleuch, to whom economics owes the subsequent leisure and independence that produced the *Wealth of Nations.* His appointment to a quasi-sinecure (1778) added ample comfort for the rest of his life. He was conscientious, painstaking to a degree, methodical, well-poised, honorable. He acknowledged obligation where honor required it, but not generously. He never uncovered the footprints of predecessors with Darwinian frankness. In criticism he was narrow and ungenerous. He had the courage and energy that exactly fit the scholar's task and go well with a good deal of circumspection.

The day of polyhistoric knowledge was not yet over: a man could then roam over the whole of science and art and even do work in widely distant fields without meeting disaster. Not less than Beccaria or Turgot, A. Smith held sway over a wide domain of which economics was only a part. We have already had the opportunity to notice his *Theory of Moral Sentiments* (1759), to which was appended (3rd ed. 1767) *A Dissertation on the Origin of Languages*—his first great success, which matured, from beginnings in the material of the Edinburgh lectures, during the first half of his tenure of the Glasgow chair, and should be recalled to make the reader immune to the silly criticism that A. Smith gave inadequate attention to the importance of ethical forces. Moreover, Smith's *philosophy* of riches and of economic activity is there and not in the *Wealth of Nations.* To this and to his work in natural law, 'natural theology,' and belles lettres must, however, be added six essays,[14] some of which are the crystallized fragments of the grandiose plan of a 'history of the liberal sciences and elegant arts' which he abandoned 'as far too extensive.' The pearl of the collection is the first essay on the 'Principles which lead and direct Philosophical Enquiries; illustrated by the History of Astronomy.' Nobody, I venture to say, can have an adequate idea of Smith's intellectual stature who does not know these essays. I also venture to say that, were it not for the undeniable fact, nobody would credit the author of the *Wealth of Nations* with the power to write them.

We know already that the skeleton of Smith's analysis hails from the scholastics and the natural-law philosophers: besides lying ready at hand in the works of Grotius and Pufendorf, it was taught to him by his teacher Hutcheson.[15] It is true that neither the scholastics nor the natural-law philosophers ever evolved a completely articulate scheme of distribution, still less the misleading idea, which was to play so great a role in the theory of the nineteenth century, of a social product or National Dividend distributed among the agents that take part in its production. But they had worked out all the elements of such a scheme, and Smith was no doubt equal to the task of co-ordinating them without further help from anyone. According to Cannan, the Glasgow Lectures—which show no great advance beyond Hutcheson in any direction—contain 'no trace whatever . . . of the scheme of distribution which the

---

[14] *Essays on Philosophical Subjects by the late Adam Smith . . .* ed. by his executors, Black and Hutton, to which was prefixed an *Account of the Life and Writings of the Author by Dugald Stewart . . .* (1st ed. 1795). Stewart, by the way, who held the Edinburgh chair of moral philosophy, 1785-1810, though he can hardly be said to have made any mark by his published writings, was so strong a personality and so effective a teacher that a more complete history of our subject could not pass him by as we must.

---

[15] On Francis Hutcheson, see above, ch. 2, sec. 7b. Also see W. R. Scott, *Francis Hutcheson* (1900). The lineage of Smith's economics has been, as we might expect, the subject of much research. A great event was the discovery and subsequent publication by E. Cannan of the *Lectures on Justice, Police, Revenue and Arms, delivered in the University of Glasgow by Adam Smith, reported by a student in* 1763 (1896), to which I shall refer as Glasgow Lectures; another was the discovery, and publication in Scott's book mentioned above, of what may be called an early draft of the *Wealth of Nations*, which, according to Professor Scott, antedates by but little Smith's departure for France and thus presumably reflects the general state of Smith's work before he came into personal contact with the French economists. It will be referred to as Draft. To Professor Cannan we owe by far the best of the many editions of the *Wealth of Nations* (1904; republished many times, 6th ed. 1950) which contains a most valuable introduction, which sheds much light on some questions of lineage. Publication of *A Catalogue of the Library of Adam Smith* (1st ed. 1894; 2nd ed. 1932) with introduction was one of the many services rendered to 'Smithology' by James Bonar.

Space forbids our dealing with matters of editions, translations, summaries, paraphrases of, and excerpts from the *Wealth of Nations*, a fact that I regret the more because the Vanderblue Memorial Collection of Smithiana in the Kress Library (see pamphlet published by the Kress Library, containing a special catalogue of this collection by Homer B. Vanderblue, prefaced with an essay by Charles J. Bullock, 1939) gave me an excellent opportunity for investigating them. Nor is it possible to do justice to the extensive literature that deals with the *Wealth of Nations*. The most valuable comments, expository and critical, are scattered all over the economic treatises and papers of the nineteenth century: it is they that make up the true monument to Smith, the scientific economist. Those economists and non economists who wrote on Smith and 'Smithianism' per se, particularly the Germans, were usually not, or not primarily, interested in his analytic performance, but rather in his views on practical issues, his philosophical backgrounds, his social sympathies. Neglecting the comments that are, of course, to be found in all general histories of economic thought, we must however notice the analyses of Smith's work by Marx, in the *Theorien über den Mehrwert*, and by Cannan, in the *History of the Theories of Production and Distribution*. In addition we may mention: J. F. Baert, *Adam Smith, en zijn Onderzoek naar den Rijkdom der Volken* (1858); A. Delatour, *Adam Smith* (1886); W. Hasbach, *Untersuchungen über Adam Smith* (1891); S. Feilbogen, *Smith und Turgot* (1892); G. R. Morrow, *The Ethical and Economic Theories of Adam Smith* (1923); W. Bagehot, *Adam Smith and Our Modern Economy* (*Works*, ed. by Mrs. Russell Barrington, vol. 7); Edwin Cannan, 'Adam Smith as an Economist,' *Economica*, June 1926; and the sesquicentennial Chicago *Lectures* (1928).

Wealth of Nations sets forth.' It is not necessary to infer from this, however, that Smith was under heavy (and largely unacknowledged) obligation to the physiocrats, whom he met (1764-6) and presumably read before he settled down to work at Kirkcaldy. The Draft discovered by Professor Scott proves that this may go too far: the Draft clearly foreshadows the scheme of the *Wealth*. On the other hand, however, it must not be forgotten that the heritage of the natural-law philosophers and the achievements of A. Smith's French contemporaries were not all he had to work with. There was the other of the two streams that meet in the *Wealth of Nations*, represented by the Consultant Administrators and the Pamphleteers. Smith knew Petty and Locke; he presumably made acquaintance with Cantillon, at least through Postlethwayt's *Dictionary*, at an early stage of his work; he laid Harris and Decker under contribution; his friend Hume's writings and Massie's must have been familiar to him; and in the long list of writers whom he affected to despise because of their 'mercantilist errors,' there are some who might have taught him a lot, for example, Child, Davenant, Pollexfen, not to insist on such 'anti-mercantilists' as Barbon and North.[16] But no matter what he actually learned or failed to learn from predecessors, the fact is that the *Wealth of Nations* does not contain a single *analytic* idea, principle, or method that was entirely new in 1776.

Those who extolled A. Smith's work as an epoch-making, original achievement were, of course, thinking primarily of the *policies* he advocated—free trade, laissez-faire, colonial policy, and so on. But, as should be clear by now and as will become still clearer as we go along, this aspect would not lead to a different conclusion even if it were relevant to our subject. Smith himself, according to Dugald Stewart, indeed laid claim (in a paper drawn up in 1755) to priority concerning the principle of Natural Liberty on the ground that he had taught it as early as 1749. By this principle he meant both a canon of policy—the removal of all restraints except those imposed by 'justice'—and the analytic proposition that free interaction of individuals produces not chaos but an orderly pattern that is logically determined: he never distinguished the two quite clearly. Taken in either sense, however, the principle had been quite clearly enunciated before, for example, by Grotius and Pufendorf. It is precisely for this reason that no charge of plagiarism can be made either against Smith or on his behalf against others. This does not exclude the possibility of course that, in stating it with greater force and fullness than anyone before him, Smith experienced subjectively all the thrill of discovery or even that, some time before 1749, he actually made the 'discovery' himself.

---

[16] Two authors should be mentioned, if only because they are mentioned so frequently. Adam Ferguson (1723-1816), professor first of 'natural' then of 'moral' philosophy in Edinburgh, was primarily a historical sociologist. His *Essay on the History of Civil Society* (1st ed. 1767), the only one of his works that need be noticed, hails from Montesquieu (to whom also Smith was indebted) and met, on a reduced scale, with the same kind of success as did the *Esprit des lois*. In Germany, partly under the influence of Marx, it enjoyed considerable—and, as it seems to me, unmerited—reputation in the nineteenth century. There is hardly any reason to believe, as did Marx, that Smith owed any considerable debt to it or, as others have held, that Ferguson owed much to Smith's lectures or conversation: the parallelisms that are adduced in support of either view concern ideas—on division of labor and taxation—which were common currency at that time and could have been drawn from a number of older authors.

Bernard de Mandeville published a didactic poem entitled *The Grumbling Hive* (1705; better known under the later title, *The Fable of the Bees: or, Private Vices, Publick Benefits*, 1714), in which he endeavored to show that the individual motives that produce socially desirable actions are not unlikely to be morally objectionable. Adam Smith, like other virtuous people, was hard on this piece of work. It contained indeed a eulogy on spending and an indictment of saving, as well as certain 'mercantilist errors' that must have displeased him. But there was more than that to his hostility. Smith cannot have failed to perceive that Mandeville's argument was an argument for Smith's own pure Natural Liberty couched in a particular form. The reader will have no difficulty in realizing how this fact must have shocked the respectable professor—particularly if it should be the case that he learned something from the offending pamphlet.

But though the *Wealth of Nations* contained no really novel ideas and though it cannot rank with Newton's *Principia* or Darwin's *Origin* as an intellectual achievement, it is a great performance all the same and fully deserved its success. The nature of the one and the causes of the other are not hard to see. The time had come for precisely that kind of co-ordination. And this task A. Smith performed extremely well. He was fitted for it by nature: no one but a methodical professor could have accomplished it. He gave his best: the *Wealth* is the product of labor ungrudgingly bestowed during more than twenty-five years, exclusively concentrated upon it during about ten. His mental stature was up to mastering the unwieldy material that flowed from many sources and to subjecting it, with a strong hand, to the rule of a small number of coherent principles: the builder who built solidly, regardless of cost, was also a great architect. His very limitations made for success. Had he been more brilliant, he would not have been taken so seriously. Had he dug more deeply, had he unearthed more recondite truth, had he used difficult and ingenious methods, he would not have been understood. But he had no such ambitions; in fact he disliked whatever went beyond plain common sense. He never moved above the heads of even the dullest readers. He led them on gently, encouraging them by trivialities and homely observations, making them feel comfortable all along. While the professional of his time found enough to command his intellectual respect, the 'educated reader' was able to assure himself that, yes, this was so, he too had always thought so; while Smith taxed the reader's patience with his masses of historical and statistical material, he did not tax his reasoning power. He was effective not only by virtue of what he gave but also by virtue of what he failed to give. Last but not least, argument and material were enlivened by advocacy which is after all what attracts a wider public: everywhere, the professor turned his chair into a seat of judgment and bestowed praise and blame. And it was Adam Smith's good fortune that he was thoroughly in sympathy with the humors of his time. He advocated the things that were in the offing, and he made his analysis serve them. Needless to insist on what this meant both for performance and success: where would the *Wealth of Nations* be without free trade and laissez-faire? Also, the 'unfeeling' or 'slothful' landlords who reap where they have not sown, the employers whose every meeting issues in conspiracy, the merchants who enjoy themselves and let their clerks and accountants do the work, and the poor laborers who support the rest of society in luxury—these are all important parts of the show. It has been held that A. Smith, far ahead of his time, braved unpopularity by giving expression to his social sympathies. This is not so. His sincerity I do not for a moment call into question. But those views were not unpopular. They were in fashion. A judiciously diluted Rousseauism is also evident in the equalitarian tendency of his economic sociology. Human beings seemed to him to be much alike by nature, all reacting in the same simple ways to very simple stimuli, differences being due mainly to different training and different environments. This is very important considering A. Smith's influence upon nineteenth-century economics. His work was the channel through which eighteenth-century ideas about human nature reached economists.

Now for the Reader's Guide: *An Inquiry into the Nature and Causes of the Wealth of Nations* by Adam Smith, LL.D. and F.R.S., formerly Professor of Moral Philosophy in the University of Glasgow, in two volumes, London 1776, defines scientific economics quite well by its title and hardly less felicitously, though less concisely, in the last paragraph of the Introduction. But in the introduction to Book IV we read that Political Economy 'proposes to enrich both the people and the sovereign,' and it is this definition which expresses both what Smith wanted above everything and what interested his readers more than anything else. It makes economics a collection of recipes for the 'statesman.' All the more important is it to remember that the viewpoint of analysis is not absent and that *we*, whatever A. Smith himself may have thought, can separate the analysis from the recipes without doing any violence to his text.

There are five Books. The fifth and longest—taking 28.6 per cent of total space—is a nearly self-contained treatise on Public Finance and was to become and to remain the basis of all the nineteenth-century treatises on the subject until, mainly in Germany, the 'social' viewpoint—taxation as an instrument of reform—asserted itself. The length of the book is due to the masses of material it contains: its treatment of public expenditure, revenue, and debts is *primarily* historical. The theory is inadequate, and does not reach much below the surface. But what there is of it is admirably worked in with the reports on general developments as well as on individual facts. Further facts have been amassed and theoretical technique has been improved but nobody has to this day succeeded in welding the two—plus a little political sociology—together as did A. Smith. The fourth Book, nearly as long,[17] contains the famous indictment of the 'commercial or mercantile system'—the patronizingly benevolent criticism of physiocrat doctrine in the ninth and last chapter does not call for comment—from the ashes of which rises, phoenix-like, Smith's own political system. Again: the reader beholds masses of facts painstakingly marshalled, very little of very simple theory (no advance whatever in this over even distant 'predecessors'), which is, however, most successfully used in lightening up the mosaic of details, in heating the facts till they glow. The facts overflow and stumble over one another: two monographs are inserted by way of digressions (on Banks of Deposit and on the Corn Trade) where they do not belong. The great and justly famous chapter 'Of Colonies' (which should be compared with the last pages of the work) falls out of line, but nothing matters: we have a masterpiece before us, a masterpiece not only of pleading but also of analysis. Book III, which occupies less than 4.5 per cent of total space, may be described as a prelude to Book IV, filling in general considerations of a primarily historical nature on the 'natural progress of opulence,' the rise and the commerce of towns as distorted—hampered or propelled—by the policies sponsored by various interests. This third Book did not attract the attention it seems to merit. In its somewhat dry and uninspired wisdom, it might have made an excellent starting point of a historical sociology of economic life that was never written. Books I and II—respectively about 25 and 14 per cent of the whole—also overflowing with illustrative fact, present the essentials of A. Smith's analytic schema. They can indeed be perused by themselves. But the reader who, more interested in theory than in 'application,' refuses to go beyond them will miss much that is indispensable for a full understanding of the theory itself.

---

[17] The fourth and fifth Books account for nearly 57 per cent of the total space.

The first three chapters of Book I deal with Division of Labour.[18] We are in the oldest part of the building, the part already completed in the Draft. Also, presumably because in his teaching Smith had so often gone over this subject, it is by far the most polished part of the whole. Though, as we know, there is nothing original about it, one feature must be mentioned that has not received the attention it deserves: nobody, either before or after A. Smith, ever thought of putting such a burden upon division of labor. With A. Smith it is practically the only factor in economic progress. *Alone* it accounts 'for the superior affluence and abundance commonly possessed even by [the] lowest and most despised member of Civilized society, compared with what the most respected and active savage can attain to' in spite of so much 'oppressive inequality' (Draft, see Scott, op. cit. p. 328). Technological progress, 'invention of all those machines'—and even investments—is induced by it and is, in fact, just an incident of it. We shall consider this feature of A. Smith's analytic schema at the end of this Reader's Guide.

Division of labor itself is attributed to an inborn propensity to truck and its development to the gradual expansion of markets—the extent of the market at any point of time determining how far it can go (ch. 3). It thus appears and grows as an entirely impersonal force, and since it is the great motor of progress, this progress too is depersonalized.

---

[18] The reader will please bear in mind that all the more important points of A. Smith's analysis that can be touched upon at all in this history will be dealt with in their proper places, excepting a few which there is no opportunity to mention elsewhere. This is nothing but a jejune and desperately brief Reader's Guide.

In Chapter 4, A. Smith completes the time-honored sequence: division of labor-barter-money and, falling far below the level reached by many older authors and particularly by Galiani, severs 'value in exchange' completely from 'value in use.' In Chapter 5 (which starts with Cantillon's definition of *richesse*) he undertakes to find a measure of the former that is more reliable than is price expressed in terms of money. Equating value in exchange to price and observing that 'price in money' fluctuates in response to purely monetary changes, Smith replaces for purposes of interlocal and intertemporal comparisons this monetary or 'nominal price' of each commodity by a real price in the same sense in which we speak, for example, of real wages as distinguished from money wages,[19] that is, by price in terms of all other commodities. And these real prices he in turn replaces, in ignorance of the index-number method already invented in his time, by prices expressed in terms of labor (after having considered corn for the role): in other words, he chooses the commodity labor instead of the commodity silver or the commodity gold as *numéraire*—to use the phrase brought into general use by L. Walras. This may or may not be helpful, but there is no logical objection to it. But Smith flounders so badly in conveying the idea and, moreover, confuses it with philosophies concerning the nature of value and real price in a different sense—see the famous doctrines about 'toil and trouble' as the real price of everything (paragraph 2 of ch. 5) and about labor alone 'never varying in its own value' (paragraph 7)—that his fundamentally simple idea was misunderstood even by Ricardo. Accordingly, he was credited with a labor theory of value—or rather with three incompatible labor theories[20]—whereas it is quite clear from Chapter 6 that he meant to *explain* commodity prices by cost of production, which in this chapter he divides up into wages, profit, and rent—the 'original sources of all revenue as well as of all exchangeable value.' This is no doubt very unsatisfactory as an explanation of value but serves well as an avenue both to a theory of equilibrium price and to the theory of distribution.

---

[19] See, e.g., the 9th paragraph of ch. 5.

[20] Though it will be necessary to return to A. Smith's view on value both in ch. 6 of this Part and in the third Part, a brief clarification of the matter in this place may prove helpful. In itself, the choice of hours or days of labor as units by which to express commodity values or prices—on the (invalid) ground that labor never varies in its own value or on any other ground—no more implies any particular theory of exchange value or price than the choice of oxen as units by which to express commodity values or prices implies an ox theory of exchange value or price. But Smith (just as R. Owen and other sponsors of the plan to make labor notes the medium of circulation) does not seem to have seen this clearly and undoubtedly argued in several places as if his use of labor as *numéraire* did imply a theory of value. Moreover, he repeatedly seems to confuse the quantity of labor a commodity will exchange for with the quantity of labor this commodity costs to produce—which is what Ricardo criticized. The quantity a commodity costs to produce then comes to the front in the famous beaver-deer example at the beginning of ch. 6, though it is but just to add that Smith confines the proposition that this quantity 'regulates' price expressly to that 'early and rude state of society' in which there are no other distributive shares to take into account. Finally, there is the 'toil and trouble' which is the 'real price of everything' and which, at least if interpreted as equivalent to the later concept, disutility of labor, agrees with neither of the two other measures. These, then, are

The rudimentary equilibrium theory of Chapter 7, by far the best piece of economic theory turned out by A. Smith, in fact points toward Say and, through the latter's work, to Walras. The purely theoretical developments of the nineteenth century consist to a considerable degree in improvements upon it. Market price, defined in terms of short-run demand and supply, is treated as fluctuating around a 'natural' price—J. S. Mill's 'necessary' price, A. Marshall's 'normal' price—which is the price that is sufficient and not more than sufficient to cover 'the whole value of the rent, wages, and profit, which must be paid in order to bring' to market that quantity of every commodity 'which will supply the effectual demand,' that is, the demand effective at that price. There is no theory of monopoly price beyond the meaningless (or even false) sentence that the 'price of monopoly is upon every occasion the highest which can be got,' whereas 'the price of free competition . . . is the lowest which can be taken' in the long run—an important theorem though Smith does not seem to have had any notion of the difficulties of a satisfactory proof. Chapters 8 to 11 complete the self-contained argument of the first Book, whose contour lines, though hidden by the luxuriant foliage of illustrative fact that often degenerates into digression, are not without beauty. They deal with 'the circumstances which naturally determine' the rate of wages and the rate of profit and 'regulate' the rent of land (p. 56).[21] These chapters, summing up and co-ordinating, handed down the theory of distribution of the eighteenth century to the economists of the nineteenth, who found it all the easier to start from them because the very looseness of Adam Smith's doctrines invited development on many different lines: Smith's very weaknesses conspired to qualify him for his type of leadership. It must suffice to draw the reader's attention to the following points.

---

the three labor theories of value or price which A. Smith is supposed to have held. However, since the first is logically incapable of serving as an *explanation* of the phenomenon of value—the reader will perceive that, considered as such, it spells circular reasoning—and since we may neglect the third, because A. Smith made no effort to develop the theme of disutility, we are really left with the second or labor-quantity theory of value. And, finally, since A. Smith—unlike Ricardo and Marx—claimed no validity at all for this except in a special case, we come to the conclusion that, in spite of his emphasis on the labor factor, his theory of value is no labor theory at all. The fact that the first sentence of the introduction makes the whole of the National Dividend a 'produce of labor,' does not affect this conclusion as a little reflection should show.

[21] [The page references in this Reader's Guide are to the Everyman's Library Edition published by J. M. Dent, London, and E. P. Dutton & Co.., New York (1910), of which there was a copy in the library in Taconic. Elsewhere J. A. S. used the Cannan edition referred to in note 15.]

Chapter 8 on wages contains not only the rudiments of both the wage fund (p. 61) and the minimum-of-existence (pp. 71, 76) theories, which might have been derived from Turgot and the physiocrats and which have been made the most of by A. Smith's English successors, but also another element, the full importance of which these successors failed to see. This is enshrined in his pithy sentence that the 'liberal reward of labour' is both 'the necessary effect' and 'the natural symptom of *increasing* [J. A. S.'s italics] national wealth' (p. 65) which, though inadequately motivated, sheds a light on the problem of wages quite different from that in which Ricardo saw it. Chapter 9 on profit offers many points about the factors that determine the rate of profit (for instance on p. 83), especially relatively to wages, but fails to face the fundamental problem. So far as Smith can be credited with having had a theory of 'profit' at all, it must be pieced together from indications, mostly vague and even contradictory, that are scattered over the first two Books. First, he definitively sanctioned and helped to victory the doctrinal tendency that was to prevail in nineteenth-century economics, particularly in England: profit, treated as the basic income of the capitalist class, is (substantially) the return from the use in business of physical goods (labor's means of subsistence included) which that class supplies; and interest on loans is simply a derivate from it. Excepting the case of the mere lenders ('monied men'), there is no distinctive function of the entrepreneurs—though Smith does speak of the 'undertaker'—or industrialists, who, 'inspection and direction' being brushed aside, are fundamentally capitalists or masters 'setting to work industrious people' and appropriating part of the product of 'their work' (ch. 6). The Marxist implications of this, which moreover Smith goes out of his way to underline, are obvious. Nevertheless, it cannot be said that Adam Smith held an exploitation theory of profit, though it can be said that he suggested it. For he also emphasized the element of risk and spoke of employers' *advancing* 'the whole stock of materials and wages' (p. 42), which points in an entirely different direction. Moreover, nobody who thought as highly of the social importance of saving as did A. Smith can complain if he be associated with abstinence-theory ideas.

In treating of the differences 'Of Wages and Profits in the different Employments of Labour and Stock' (ch. 10), Smith, reveling in facts and arguments of a somewhat trite sort, improved upon Cantillon and succeeded in creating a standard chapter of the nineteenth-century textbook. Chapter 11, 'Of the Rent of Land'—Smith, and following him, practically all the English economists to Marshall's epoch, confined the concept of rent to land and mines—is swollen by a gigantic digression (or a cluster of digressions or monographs) that makes up about 7.6 per cent of the whole work. If the vast materials and the almost innumerable disquisitions on particular points be boiled down, a mosaic of ideas emerges of which these are the outstanding elements. First, reasoning from his cost theory of value, Smith not unnaturally—though wrongly—arrives at the conclusion that the phenomenon of rent can be due only to a 'monopoly' in land (p. 131), thus starting on its career an idea that was to find sponsors again and again and has not even yet died out. But second, we find (p. 132) the statement that, whereas 'high or low wages and profit are the causes of high or low price; high or low rent is the effect of it,' which fits but ill with the monopoly theory and points in the Ricardian direction: the so-called Ricardian theory of rent *might* have emerged from an effort to put logical order into the Smithian jumble. And, third, there is even a suggestion that might have induced a disciple to straighten out that jumble by means of a productivity theory (see, e.g., p. 133). All this is intermingled with other ideas, good and bad—for example, the old idea which was as persistent as it was useless and which we encounter again in Malthus, that the production of foodstuffs holds a unique position in that it creates its own demand because people will multiply as it expands —that enter and leave the stage much as does the Falstaff crowd in *Henry IV*. Even before the reader gets to the digressions on the value of silver and on the relation between the values of silver and gold, the chapter contributes much to Smith's theory of money, which cannot however be fully mastered without reading the whole work (see especially ch. 2 of the second Book and the important Digression Concerning Banks of Deposit in ch. 3 of the fourth). Two more points should be added: at the end of the digression on silver Smith tries to show why, at least on the whole, the price—the real price— of agrarian products will rise in consequence of the Progress of Improvement (pp. 198 et seq.) and, in an additional digression (pp. 224 et seq.), that the real price of manufactures will fall. In a sense, this foreshadows the nineteenth-century doctrine of decreasing returns in agriculture and increasing returns in industry toward which he may be said to have cautiously felt his way and which *might* have been distilled from his pages. Furthermore, he arrived at the Ricardian conclusion (p. 229), though it does not follow cogently from his muddled argument, that landowners benefit in the process directly, both because the real value of the products of the land rises and because they receive a larger relative share of these products; and in addition indirectly, owing to the fall of the real price of manufactures. Laborers also benefit (p. 230) because their wages rise and the prices of part of the commodities they buy fall. But the third class, the 'merchants and master manufacturers' (p. 231), suffer, because, as A. Smith said, the *rate* of interest tends to be low in rich countries and high in poor countries, so that the interest of this class conflicts both with the interests of the other two and with the 'general interest of the society.' This was evidently intended for a schema of economic class interests such as many later economists tried to construct, possibly inspired by A. Smith's example and by a desire to correct his mistakes.

The second Book presents the theory of capital, saving, and investment that, however much transformed by development and criticism, remained the basis of practically all later work until, and partly even beyond, Böhm-Bawerk. It certainly looks like a new wing added to an old structure. In spite of the weak attempt made in the introduction to link it to the first Book by means of another and quite unconvincing appeal to 'division of labour,' there is no reason to believe that any essential part of it was either written or planned before A. Smith's stay in France. Specifically physiocrat influence is much more definitely recognizable than it is in any part of the first Book, both in many details and in the conception as a whole. This statement must not be misunderstood, however. A. Smith was not in the habit of accepting passively what he read or heard: he read and listened judicially, criticized vigorously, and in so doing arrived at a conception of his own. This is why I have spoken of physiocrat influence only, and not also of his being influenced by Turgot. Turgot holds priority in essential points, but it does not follow that Smith derived his views from him. For these views are such as would naturally emerge in Smith's mind from a creative criticism of Quesnay's teaching so that, in the absence of cogent evidence to the contrary, it seems more just to speak of parallelism than of dependence. Space forbids our presenting more than a single illustration. The Scotsman's common sense took offense at Quesnay's statement that only agricultural (and extractive) labor was productive. From Turgot he might have learned how to shrug his shoulders at this vagary and to pass on with a graceful bow. This, however, was not his way. He took things not only seriously but also literally. He had to embark upon ponderous refutation. But in his meditations on the subject it may have occurred to him that there was something to the distinction between productive and unproductive labor.[22] And so he worked out his own interpretation of it and substituted it for Quesnay's. In a sense it was suggested to him by Quesnay—this is indicated by the fact that there is no hint of it in the first Book though it would naturally belong there—but in another sense it was his own.

Chapter 1 of the second Book distinguishes that part of a man's—and society's—total stock of goods that is to be called capital (not only physical goods, since 'the acquired and useful abilities of all the inhabitants' are capital) from the rest; introduces the concepts of fixed and circulating capital; and classifies the goods that are to come under both headings, including in circulating capital money but not the means of subsistence of productive laborers, although Smith's argument calls for and actually implies inclusion of the latter. The long Chapter 2, one of the most important of the work, contains the bulk of A. Smith's theory of money. It is much above Chapter 4 of the first Book and certainly the result of a late stage of A. Smith's labors. But it displays no physiocrat influence—all recognizable influence is English. Chapter 3 (which introduces the distinction between productive and unproductive labor), with its tremendous emphasis on the propensity to save as the true creator of physical capital ('Parsimony, and not industry, is the immediate cause of the increase of capital,' p. 301; 'every prodigal appears to be a public enemy, and every frugal man a public benefactor,' p. 304), marks the victory for more than 150 years to come of a pro-saving theory. 'What is annually saved is as regularly consumed as what is annually spent, and nearly in the same time too; but it is consumed by a different set of people' (p. 302), namely, productive laborers whose wages and employment are thus positively related to the rate of saving which is identified or at least equated to the rate of increase of capital, that is, investment. In this chapter, revenue means profit plus rent, exactly as it does with Marx. Chapter 4 tackles the problem of interest. Since, as indicated above, profit is treated as the fundamental phenomenon and this is taken for granted here, interest simply follows from the fact that money—but, as Smith holds, really the producers' goods and services that can be bought for it—always meets with demand at a premium motivated by the expectation of profits. Smith as well as all his successors until recent times simply saw no difficulty in explaining interest per se: the difference between him and his nineteenth-century successors was only that he did not see much of a problem in business profit either, whereas, as time went on, an increasing number of the latter began to worry about it. There are thus but three points to mention: first, his unconvincing explanation of the tendency of the rate of interest to fall by the increasing competition between increasing capitals; second, his vigorous, and for 150 years successful, argument against the monetary theories of interest that attempt to explain that tendency by the increase in the quantity of monetary metals; third, his moderate and judicious argument about legal maxima which called forth an entirely unjustified attack from Bentham.

---

[22] It may be just as well to state at once what that something was, because both A. Smith's clumsy and inconsistent handling of it and the nineteenth-century controversy on this distinction have needlessly obscured its meaning. Productive laborers reproduce the value of the capital that employs them with a profit; unproductively employed laborers either sell their services or else produce something that does not yield profit. This may be considered as the embryo of Marx's theory of surplus value. Interpreted in this sense, this distinction is not irrelevant. But Smith himself has to take the blame if this meaning of it, which is quite clear from the first paragraph of ch. 3, did not stand out from all the irrelevancies with which he associated it. From another but cognate standpoint the distinction is between labor that does and labor that does not produce something that must be sold in order to complete the transaction: when a personal servant has sold his services to his employer and has received payment *out of the latter's income*, there is no further step in the process; if the same man secures employment in a shoe factory, he is paid out of capital and the process in which his work is an element is not completed until the shoes have found a buyer.

[The Reader's Guide was not completed. There is, for example, no discussion of ch. 5 (Of the different Employment of Capitals), the concluding chapter of the second Book. The final paragraph was on a separate sheet with no indication as to its intended position.]

Before the century was out the *Wealth of Nations* had run to nine English editions, not counting the ones that appeared in Ireland and the United States, and had been translated (so far as I know) into Danish, Dutch, *French*, *German*, Italian, and Spanish (italics indicate more than one translation; the first Russian translation appeared 1802-6). This may be taken to measure the extent of its success in the first stage of its career. For a work of its type and calibre—which entirely lacked the graces of the *Esprit des lois*—it can, I think, be called spectacular. But this was as nothing compared with the really significant success that is not so easy to measure: from about 1790 on, Smith became the teacher not of the beginner or the public but of the professionals, especially the professors. The thought of most of them, including Ricardo, started from him and most of them again never got beyond him. For half a century or more, roughly until J. S. Mill's *Principles* (1848) started on its career, Adam Smith supplied the bulk of the ideas of the average economist. In England, Ricardo's *Principles* (1817) meant a serious check. But outside of England, most economists were not quite up to Ricardo, and Smith continued to hold sway. It was then that he was invested with the insignia of 'founder'—which none of his contemporaries would have thought of bestowing on him—and that earlier economists moved into the role of 'precursors' in whom it was just wonderful to discover what nevertheless remained Smith's ideas.

5. Quasi-Systems

Lest the reader should conceive an entirely wrong impression—which if it be allowed to settle in his mind the subsequent chapters might be powerless to dispel—it is necessary to supplement without delay the story told in the preceding section by at least some account of the parallel stream of quasi-systems. Most of them, as we know, were programs of industrial and commercial development. Their authors recommended or fought policies appropriate or inimical to those programs, and reasoned in terms of individual problems. But their ideas were not unsystematic in the sense of lacking coherence. They knew how to relate one problem to another and to reduce them to unifying principles—*analytic* principles, not merely principles of policy. If these analytic principles were not always stated explicitly, they were nevertheless often worked out effectively in a way that suggests the development of English law. In this section, we shall confine ourselves to a selection of seventeenth-century writers, all of whom will have to be mentioned again as we go along. Many more will be introduced in the next and later chapters.

The honors of this literature—for the seventeenth century—belong to English businessmen and civil servants but the list is headed by an Italian, Serra.[1]

---

[1] Antonio Serra, *Breve trattato delle cause che possono far abbondare li regni d'oro e argento dove non sono miniere* (1613; republ. in the Custodi collection and in A. Graziani's *Economisti del cinque e seicento*, 1913; by extract also in G. Tagliacozzo's *Economisti Napoletani dei secoli XVII e XVIII*, 1937, with summary and appraisal, English trans. in A. E. Monroe's *Early Economic Thought*). Nothing is known of the author except that he wrote the treatise in a Neapolitan prison, perhaps in the hope of regaining his freedom thereby, for it is dedicated to the Spanish Viceroy. Again—as in the case of L. Ortiz, who might be claimed as a predecessor of Serra as might also another Spaniard, Gonzáles de Cellorigo (*Memoriales. De la politica necesaria . . . á la república de España*, 1600), both of whom, however, lacked Serra's grasp of principle—the reader is asked to forget the title, which evidently was chosen in order to interest the Viceroy and does not express the gist and importance of the argument at all well. However, there was some justification for it: the author argued at length against the exchange-control policy advocated by De Santis—not entirely successfully—so that the treatise has also a place in the history of the 'mercantilist' controversies (see below, ch. 7). On Serra and his work, see R. Benini, '*Sulle dottrine economiche di Antonio Serra*,' *Giornale degli Economisti*, 1892. Further references in Tagliacozzo's edition.

This man must, I think, be credited with having been the first to compose a scientific treatise, though an unsystematic one, on Economic Principles and Policy. Its chief merit does not consist in his having explained the outflow of gold and silver from the Neapolitan Kingdom by the state of the balance of payments but in the fact that he did not stop there but went on to explain the latter by a general analysis of the conditions that determine the state of an economic organism. Essentially, the treatise is about the factors on which depend the abundance not of money but of *commodities*—natural resources, quality of the people, the development of industry and trade, the efficiency of government—the implication being that if the economic process as a whole functions properly, the monetary element will take care of itself and not require any specific therapy. And this argument contains several contributions to the nascent stock of theoretical tools that will be noticed later.[2]

For several decades, there was nothing like this anywhere. But in the second half of the century we behold a rich crop of works of a similar type in England, the standard title of which was, as mentioned already, *Discourse of Trade.* Gradually their authors discovered for themselves pieces of the logic inherent in the economic process: the things which they could have learned from the scholastics and their successors and which, under different circumstances and, accordingly, from the standpoint of different political aims, were to become the rationale of the doctrines of laissez-faire liberalism. A landmark on this way was Child's *Discourse.*[3] This outstanding performance was and is usually disposed of as one of the many 'mercantilist' writings—which was and (to some extent) still is sufficient to prevent many historians from seeing any merit in it. But quite independently of whether or not that label fits, it should be recognized that this *Discourse* deals with the practical problems of its time—employment, wages, money, exchanges, exports and imports, and so on—in the light of clearly adumbrated 'laws' of the mechanism of capitalist markets; though not explicitly worked out, the tool that we call equilibrium theory is, as it were, present behind the scene. This performance was matched and in many individual points surpassed by such men as Barbon, Davenant, North, Pollexfen, and others.[4] In every one of these cases we see more or less awareness of the existence of an analytic apparatus that runs on in essentially the same manner, whatever the practical problem for the sake of which it is set working, and more or less willingness and ability to use it. For us this is what matters: whether we like or dislike the practical recommendations that are supposed by the authors to follow from their analysis is entirely immaterial.

---

[2] Almost immeasurably inferior to Serra in grasp of economic principle and analytic power, but not dissimilar from him in views on the issues of practical policy, was B. de Laffemas, who wrote around 1600 (for a list of his writings see F. Hayem, *Un Tailleur d'Henri IV, Barthélemy de Laffemas,* 1905; also see H. Hauser, 'La liberté du commerce et la liberté du travail sous Henry IV,' *Revue historique,* 1902).

[3] Sir Josiah Child (1630-99). That work eventually appeared in its final form under the title New Discourse of *Trade* (1693), but to do justice to its historical merit we must take into account the fact that it took decades to mature into that form. The first draft, *Brief Observations concerning Trade and Interest of Money* and also *A Short Addition* were published in 1668. Ten chapters were added, 1669-70. Those years are the relevant ones for questions of priority, because the *Discourse about Trade* that was published in 1690 did not add or alter very much. The *New Discourse* of 1693 contains still fewer alterations and adds nothing except a new introduction. A minor publication written in defense of the trade of the East India Company also merits notice. Child's reputation as an economist, besides suffering from the general prejudice against 'mercantilist' writings, also suffered from a fact that is of great interest to the sociologist of science. Child was a leading businessman, in fact the very incarnation of the most hated big business of that age: he was chairman and for some years the undisputed leader of the East India Company, besides being personally very wealthy. Accordingly, he was unpopular in his time, and so he has remained for over 250 years, historians being careful to clear their skirts of the 'monopolist' and 'special pleader' (*scilicet* for his personal interest).

I take this opportunity to mention a remarkable though little-known treatise on foreign trade which Professor Foxwell (see Kress Library of Business and Economics, Harvard Graduate School of Business Administration, Catalogue) described as 'one of the earliest formal systems of political economy, and stating one of the most forcible practical arguments for free trade,' though the latter part of Foxwell's statement seems to me more true than the former: Isaac Gervaise, *The System or Theory of the Trade of the World* (1720). Professor Viner (see below, ch. 7) has done full justice to this remarkable contribution to the theory of international trade whose author outlined in addition—all in the space of 34 pages—the topics of general theory germane to his particular subject, though of course not in any 'formal' layout.

The common run of these discourses was, however, far below that level. Most of them were merely motivated programs for the industrial and commercial development of England. Since foreign trade occupied the place of honor and most of the space in those programs, a selection of works of this type will be noticed in the last chapter of this Part. For the moment it will suffice to mention by way of example the tracts of the overrated Mun (his title was, however, not Discourse of Trade but *England's Treasure by Forraign Trade*, 1664), of

---

[4] References will be given in subsequent chapters. However, Charles Davenant's contribution must not be appraised from his *Discourses on the Publick Revenues, and on the Trade of England* (1698), but rather from all his many publications taken together: they sum up to a comprehensive quasi-system. And Pollexfen will be commented on at once. John Pollexfen was a merchant and M.P., who also served on the Board of Trade. In addition to his principal work, *A Discourse of Trade, Coyn, and Paper Credit* (1697, reprinted 1700), he also wrote *England and East India Inconsistent in their Manufactures* (1697), a tract that, besides attacking his *bête noire*, the East India Company, in reply to Davenant's *Essay on the East-India-Trade* (1696), complements part of the argument of the *Discourse*. The latter is an excellent piece of work, precisely as regards analytic ability. It is therefore a question of some interest to ask why he has received so little recognition and especially why such recognition as he received has been tempered in most cases by derogatory comments upon his supposed lack of originality and upon his various 'mercantilist errors.' The latter indictment seems without foundation, and concerning the former it is sufficient to ask: if we define eminence in an economist solely by the presence in his writings of entirely new results, where will A. Smith be, or Ricardo, or J. S. Mill?

Cary, and of Petyt.[5] There was no lack of unity about them as to political vision. And this vision was quite comprehensive, embracing all the economic problems of the nation. But there was no analytic work, and faults of reasoning abound. Cary, for instance, besides discussing carefully the conditions and possibilities of English trade with each foreign country, with Ireland, and with the colonies (the most valuable part of the tract) also concerns himself with monopolies (that is, the monopolies of the great trading companies), the causes of and remedies for unemployment, coinage, credit, and many other subjects down to the problem—or was this Mrs. Cary's contribution?—of how to make maid servants 'more orderly and governable than now they are' (p. 162). But every attempt he makes to carry analysis beyond the obvious is a failure. High rents, for instance, are made responsible for England's being undersold in foreign markets. High interest is held to be another cause of this but without recourse to any argument that might raise this theory above the status of a popular observation. In spite of the emphasis on export surpluses, high prices and high wages are commended on grounds that tax the reader's capacity for generous interpretation. And so on. Yet there is plenty of shrewd sense about it all—shrewd, narrowly nationalistic, and naïvely brutal (compare, for example, his enthusiasm for the slave trade, England's 'silver mine,' p. 76, or his views about the treatment to be dealt out to Ireland, *passim*).

Once we have learned to discern 'quasi-systems' in or behind writings that profess to deal only with particular problems, we find the genus everywhere. In the Netherlands, for instance, Graswinckel's and de la Court's[6] writings belong to it, although the former dealt only with the grain trade. Many historians will place them above their English contemporaries on account of their 'liberal' views on national and international trade—though de la Court lapsed from grace as to the latter—government interference, medieval corporations, and so on. But we shall arrive at a substantially similar estimate because of those authors' clear perception of causes and effects in all matters of the price mechanism. A man who in 1651 recognized the economic function of 'forestalling' and speculation, as did Graswinckel, knew something that could have been presented as a discovery in 1751—not that it would really have been one—though it was a commonplace in 1851 and will sound altogether wrong now.

---

[5] John Cary, merchant in Bristol, *An Essay on the State of England in Relation to its Trade, its Poor, and its Taxes . . . .* 1695, the edition used. There were several others—the one of 1745 bearing the title *Discourse on Trade*—which points to considerable success. For Locke's praise of the performance I can only account by the fact that Cary favored recoinage of the currency at the old standard of weight and fineness and that, in 1695, Locke would have welcomed *any* writer who did so (see below, ch. 6). Perhaps, however, he was also attracted by Cary's careful discussion of England's trade with various countries. The other work, *Britannia Languens, or a Discourse of Trade . . .* (1680), appeared under the pseudonym Philanglus and is attributed to William Petyt on Professor Foxwell's authority (see Catalogue of the Kress Library).

[6] Dirck Graswinckel (1600-1666), a lawyer and public servant, wrote a treatise on the economics of the food trade under the unpromising title: *Placaetbook op het stuk van de Leeftocht* (Compilation of regulations concerning food, 1651). Pieter de la Court (1618-85) was a manufacturer. Of his works it is only necessary to mention the *Interest van Holland . . .* (1662; 2nd ed. under the title *Aanwysing . . .* 1669).

German seventeenth-century writings of this genus, besides taking, of course, a different view as to policy, were not on this level but there were many of the Cary type or better. We shall be content with an Austrian representative, the well-known Hornigk,[7] who, like the much more important Becher and some others, figures in every history of economics. His book is another program for a policy of fostering economic development, written this time for a poor country, perennially threatened by Turkish invasions and lacking both the resources and the possibilities of England. If, however, we take due account of this fact, the family likeness of the recommendations with those of Hornigk's English contemporaries—or even with those of the doctor in the *Discourse of the Common Weal*—is striking: waste lands and other unused resources are to be exploited; the efficiency of labor is to be increased by better training; domestic industry should be helped, among other things, by directing consumers' demand toward its products; exports of manufactures and imports of necessary raw materials should be favored, exports of the latter and imports of the former restricted; trade should be balanced bilaterally with every individual foreign country (see last chapter of this Part); and so forth—sound sense all or most of it and very interesting as a monument of the intelligent bureaucrat's thought, but sound sense that did not even suspect that it might be usefully reinforced by analysis.

As regards the United States, there is nothing to record in the way of systematic endeavor before the nineteenth century. This is as we should expect from environmental conditions that were unlikely to produce either a demand for or supply of general treatises. But discussion of current practical problems was active even in colonial times, and for the eighteenth century, reports, pamphlets, and tracts abound, especially on questions of paper money, coinage, credit, trade, and fiscal policy.[8] And some of these performances

[7] *Oesterreich über Alles wann es nur will* (1684). Philipp W. von Hornigk (1638-1712) was a civil servant. Extracts from the book are included in A. E. Monroe's *Early Economic Thought*.

[8] The late Professor Seligman's essay, 'Economics in the United States,' reprinted as ch. 4 of his *Essays in Economics* (1925), gives a selection of titles (unfortunately little more than titles) on which I cannot hope to improve. Such reading as I have done was primarily guided by this selection. Also see C. F. Dunbar, 'Economic Science in America, 1776-1876,' in the *North American Review*, 1876, and the reprints of a number of the more important pamphlets by the Prince Society, 1911 (ed. McFarland Davis). American economists seem on the whole to have been too ready to discount the importance of that early literature from a scientific standpoint, and most of the attention it has received is confined to the policies or particular measures advocated or attacked. The critical historian then commends or blames according to his personal views on those policies and measures. The specifically analytic contribution of a writer as a rule goes by the board, especially in those cases where, as often happens in the field of money, 'unsound' practice goes with sound theory and vice versa. However,

answer to our idea of 'quasi-systems.' Here are three examples which the American reader is advised to look up for himself. First, Hamilton's famous *Report on Manufactures* (1791),[9] though no doubt intended as a description with a program, is really 'applied economics' at its best and reveals quite clearly essentials of the analytic framework that was to be made explicit by D. Raymond and F. List and in turn points back to the work of such men as Child and Davenant. Second, Coxe's work comes near to actually being a systematic treatise.[10] Third, Benjamin Franklin's (1706-90) various tracts on economic subjects[11] present material enough to enable us to reconstruct his system—on the practical side, substantially of a laissez-faire type—though there is little to commend for purely analytic virtues.

6. Public Finance Once More

In the first section of this chapter, the fact was emphasized that in the rising national states public finance acquired not only paramount importance but also a new significance. There would be little exaggeration in saying that,

---

within the plan of this book, very little can be done to remedy this state of things. [J. A. S. wrote this chapter before the publication of Joseph H. Dorfman's work, *The Economic Mind in American Civilization*, the first two volumes of which cover the period 1606-1865. J. A. S. read the first volume and made notes which he intended to use in revising the chapter.]

[9] Alexander Hamilton's (1757-1804) brilliant figure is so familiar to the reader that it would be absurd to tell him who and what Hamilton was. Nor is there any need to refer to the Hamilton literature. All that needs to be said from the standpoint of our purpose is that he was one of those rare practitioners of economic policy who think it worth while to acquire more analytic economics than that smattering that does such good service in addressing audiences of a certain type. He knew Smithian economics well—not only A. Smith himself—so well in fact as to be able to mold it to his own visions of practical possibilities or necessities and to perceive its limitations. All his reports—not only the one mentioned in the text but also the ones on the import duty (1782), public credit (1790 and 1795), the establishment of a national bank (1790) and of a mint (1791)—are much more than untutored common sense. Perusal of the volumes of the *Federalist*, the periodical in which he co-operated with Madison and Jay, is strongly recommended: the American reader will get much more out of it than mere economics. For guidance in starting a study of Hamilton's writings, see P. L. Ford, *Bibliotheca Hamiltoniana* (1886), and the life by H. C. Lodge (1882).

[10] Tench Coxe (1755-1824), Commissioner of Revenue, *A View of the United States* . . . (1794), in form a collection of essays and addresses.

[11] Particularly, *Modest Inquiry into the Nature and Necessity of Paper Currency* (1729); *Observations concerning the Increase of Mankind* . . . (1751); *Positions to be Examined concerning National Wealth* (1769; the work responsible for the opinion that this great realist was a physiocrat). But though these are, with the possible exception of his *Reflections on the Augmentation of Wages*, his only works that come at all within the category of economic research, other essays and much material that he contributed in a popular form to popular publications (such as *Poor Richard's Almanack*) help to round off our knowledge of his opinions and analytic efforts (*Works*, ed. by John Bigelow, 1887-8). Of course, it would be still more absurd than it would

at least for the continental branches of the literature that have been surveyed, it was the central topic around which revolved most of the rest. Let us therefore retrace our steps and look more closely at the financial problem of these centuries.

Public finance in our sense, and especially modern taxation, first developed in the course of the fifteenth century in the Italian city-republics, Florence in particular, and in the German free towns (*Reichsstädte*). More important for us is, however, the development of the fiscal systems of the national states and the Italian and German principalities. For the sake of both brevity and concreteness we shall think primarily of the case of the latter or, still more precisely, of the development of public finance in a typical *temporal* principality of Germany. Of course, people always recognized the existence of some interests that were common to all members of a political unit—recognition of the *res publica* was fostered, among other factors, by scholastic teaching. Nevertheless, public affairs were in legal principle the affairs of the territorial ruler. Wars in particular were his personal quarrels (compare the English official phrase that still survives, 'the King's enemies'). Hence, so far as the military service that his vassals owed to him proved inadequate—and this resource petered out in the course of the sixteenth century—he had to finance them from his own means. These consisted, first, of the feudal income from his own lands and, second, of a number of customary fiscal rights that went with the lordship of a principality, such as seigniorage, tolls, and customs, the right of charging for safe conduct of travelers and caravans of merchants, the right to levy taxes from Jewish communities for the protection extended to them, and rights to a wide variety of fees of all sorts (*regalia*).

The rise in prices, the cost of mercenaries and later on of standing armies, profuse expenditure on court nobilities and bureaucracies, and other causes, all related to the political ambitions of those princes or else to the social structure of their territories, rendered these customary sources of revenue inadequate and led to a rapidly mounting burden of debt. In the untenable situations that ensued the princes appealed to their Estates on the plea that, for instance, a Turkish invasion was after all not only the private affair of the prince. The Estates thereupon granted subsidies which, apart from the contributions of the towns, they levied upon their own *feudal* income, that is, upon the dues their peasantries owed to them—land in their own management remaining free. At first they insisted each time that they were making the grant of their own free will in response to a humble request and only for the particular emergency in question; but they actually bore the burden. Very soon, however, regular recurrence of these direct taxes had to be recognized. But, while accepting the fact, the Estates, on the one hand, set up their own administrations for levying them and expending the proceeds and, on the other hand, no longer bore them themselves but collected them in turn from their dependent peasantries.

---

have been in the case of Hamilton to dilate on the life and achievements of this household figure, particularly in view of the recent publication of a masterly life by Carl Van Doren.

This arrangement, besides being inadequate, was of course not at all to the taste of the princes and their bureaucracies. A tug of war between them and the Estates ensued for the control of this new fiscal apparatus that had grown up alongside of their own. The reader knows that the English parliament succeeded in keeping its hold on these purse strings which eventually in the seventeenth century throttled the power of the king. In most other countries, however, kings and princes, or rather their bureaucracies, won out in the course of the eighteenth, though the French *ancien régime* broke down in the attempt to secure fiscal reform.

Meanwhile, that is to say, until the bureaucracies had conquered the fiscal stronghold of the Estates, the growing Leviathan had to feed on the old sources of revenue. Accordingly, development of these, especially of all the fiscal rights, became a major task of governments and their henchmen. This meant eventually the disproportionate growth of indirect taxation, especially in the forms of the General Excise on the one hand, and of the General Turnover Tax—the Spanish *alcavala* is the outstanding instance—on the other. For though the introduction or increase of indirect taxes, too, was in principle dependent upon the consent of the Estates, it proved, nearly everywhere except in England, easier to get round this requirement in the case of indirect than it was in the case of direct taxation. Princes and bureaucracies had also another motive for preferring the former. We are accustomed to looking upon indirect taxation as contrary to the interests of the relatively poor. But in the seventeenth and eighteenth centuries the 'social' argument told in favor of indirect taxation: for indirect taxes were at least *also* borne by the nobility and the clergy whereas these classes contributed hardly anything at all to the proceeds of direct taxation. However, since it was not easy to introduce or reform indirect taxes either—which, by the way, shows how far those monarchies were from being 'absolute'—revenue from this source had to be increased according to opportunity rather than to any rational plan. And since, furthermore, governments were rarely in a position to abandon revenue from old fiscal rights however irrational, burdensome, or vexatious, the result was an almost unbelievable—the only word is 'mess,' the mere straightening out of which was an extremely difficult task which, when taken in hand in the seventeenth and eighteenth centuries, exercised the ingenuity of administrators and writers alike. The literature that blossomed forth in response to these conditions contains some analysis on such problems as incidence of taxes, which will be briefly noticed later on, and also analysis of a kind that had better be noticed right now, along with those much larger parts of that literature which are not relevant to a history of analytic economics and have to be mentioned only to be dismissed.

First, the tug of war referred to produced innumerable books and pamphlets on the right to tax, the 'justice' of taxation, and the constitutional questions germane to taxation. We have already remarked on the important prelude to this that is contained in the scholastic writings. The laical literature of this type displays a characteristic difference in tendency between its English branch and its continental branches: most of the continental writers sided with the bureaucracies and often saw benighted and antisocial resistance of class interest where the vast majority of English writers—particularly in the struggle over the ship money of Charles I—saw a meritorious stand for liberty. All this was, however, either simple politics or 'political philosophy' and is of no interest to us. Second, pure description of sources of public revenue and administrative practice dates far back. There is an English instance for the twelfth century.[1] This literature developed greatly from the sixteenth century on, especially on the Continent, but needs no further attention for our purposes.[2] Third, the necessity of making the most of existing fiscal rights produced in the public service a special type of lawyer whose task it was to safeguard, extend, and systematize those rights by appropriate interpretation and who naturally also taught and wrote, creating what is known as Fiscal Jurisprudence.[3] A fourth category consisted of the fiscal planners—the numerous writers who advocated schemes of fiscal reform: every financial emergency or controversy since the fifteenth century naturally produced clusters of them. In the light of their ideas it would be possible to write not only a history of public finance but also a history of political society, for everything that happens in the political sphere reflects itself more truly in the prevailing ideas about fiscal policy than it does in anything else. Most of the planners did no analytic work, however. This is especially true of some of the most eminent ones among them, such as Cardinal Cusanus, who proposed a scheme that would in fact have rescued the German Empire from the decay into which it was falling in the fifteenth and sixteenth centuries. But some did analyze. They analyzed the nature of taxation—an early example, Mattheo Palmieri's theory, has been mentioned already; its economic effects; the severity of pressure exerted by different systems; the effects of public expenditure; the relative merits of direct and indirect taxation and of financing of wars by taxation, borrowing, and inflation; and so on. Spanish discussion of the seventeenth and eighteenth centuries would be particularly interesting to follow,[4] English discussion on seventeenth and eighteenth-century war finance or on Sir Robert Walpole's excise scheme is no less so. But from the mass of this literature we shall select only two works of first-rate importance. Petty's treatise on taxes and contributions (discussed in the following chapter) is not one of them because the interest it presents, though great, belongs in the field of general economics rather than in that of fiscal policy.

---

[1] Richard Fitzneale *Dialogus de scaccario* (exchequer), ed. by Hughes, Crump, and Johnson (1902).

[2] By way of example we may mention Anon., *Traicté des finances de France* (1580); N. Froumenteau, *Le Secret des finances de France* (1581), more interesting for the finances of the temporal and spiritual magnates than for the finances of the king; Jean Combes, *Traicté des tailles et autres charges . . .* (1586); Jean Hennequin, *Le Guidon général des finances* (1585, re-edited repeatedly, even as late as 1644); J. Matthias, *Tractatio methodica . . . de contributionibus* (1632); H. Conring (whom we shall meet again), *De vectigalibus et aerario* (1663). The last two are not merely descriptive, however, though all their interest lies in the description.

[3] This branch of public-finance literature, which in the nineteenth century swelled to dimensions beyond the range of anyone but the full-time specialist, should really not be dismissed so cavalierly. But we have no choice. In my—very likely erroneous—opinion, the classic of the genus is Caspar Klock's *Tractatus juridico-politico-polemico-historicus de aerario* (1651). Its quaint title has the merit of expressing exactly what it is. C. Besold's (see above, sec. 4) earlier *De aerario publico discursus* (1615) should, however, not go unmentioned. It contains, as does Klock's, quite a lot of sound wisdom on tax policy that is as trite as, alas and alack, sound wisdom mostly is.

The first is one of the works that were called forth by the economic situation of France during the last twenty years of the reign of Louis XIV. The War of the Spanish Succession following upon the War of the Grand Alliance was turning impoverishment into nationwide misery when one of the great figures of the state and the army, the soldier-engineer Vauban, committed the indiscretion of publishing an old idea of his, the *Projet d'une dixme royale* (1707).[5] This is one of the outstanding performances in the field of public finance, unsurpassed, before or after, in the neatness and cogency of the argument. The recommendation itself does not greatly matter here. Essentially it was that the unwieldy and irrational welter of taxes that had grown up in an entirely unsystematic way should be scrapped—excepting a rationalized salt tax, certain excises, and export and import duties—and replaced by a general income tax that was to apply to all kinds of income, though at varying rates, of which the highest was to be 10 per cent (hence the word *dixme*); similar ideas had occurred before. The features that do matter are these. First, Vauban rose fully to those heights, trodden by so few, from which fiscal policy is seen to be a tool of economic therapeutics, the ultimate result of a comprehensive survey of the economic process. With Gladstonian vision he realized that fiscal measures affect the economic organism right to its cells and that the method of raising a given amount of revenue may make all the difference between paralysis and prosperity. Second, he based his conclusions in every detail on numerical fact. His engineer's mind did not guess. It figured out. Purposeful marshalling of all the available data was the essence of his analysis. Nobody ever understood better the true relation between facts and argument. It is this that makes him an economic classic in the eulogistic sense of the word, and a forerunner of modern tendencies, though he contributed nothing to the theoretical apparatus of economics.[6] His case affords another illustration of

---

[4] It turned mainly on the remedy to be applied to the grievances concerning the *alcavala*, the *cientios*, and the *millones*. Bautista Dávila (*Resúmen de los medios prácticos para el general alivio de la monarquía*, date of writing unknown, publ. 1651; see Colmeiro's *Biblioteca*) seems to have been one of the earliest economists—ignorance prevents me from being more precise—to look upon a single tax as the wand by which to conjure up the benign spirits of fiscal order. In any case his *Resúmen* is a milestone on the road to single-tax ideas. In his case, it was to be a graduated capitation tax, evidently meant to be a rough approximation to a proportional income tax. Similar ideas were discussed during the subsequent hundred years. The minister Ensenada (A. Rodriguez Villa, *Don Cenon de Somodevilla, Marqués de Ensenada*, 1878) made a modified version of this program his own and carried an income and property tax in 1729 (for Catalonia). But elsewhere and particularly in Germany, seventeenth-century discussion favored the general excise against direct taxes, precisely on the ground that it would relieve the pressure of taxation. An interesting symptom of this trend of opinion was the success of a book by an author who styled himself Christianus Teutophilus: *Entdeckte Gold-Grube in der Accise* (a gold mine discovered in the excise, 1685, of which the 5th ed. came out in 1719). Among English advocates of the excise Davenant was first in eminence. But he thought that the burden would fall on the land. For a similar reason, F. Fauquier (*An Essay on the Ways and Means* . . . 1756) later on advocated a house tax, namely on the ground that, since indirect taxes so far as they are paid by the poor will be transferred to the rich by means of a rise in money wages, taxes should be laid on where they will rest without giving rise to the losses incident to the process of transference. Observe that this anticipates much of what A. Smith and Ricardo had to say on the subject. In appraising attitudes toward the taxation of land it must not be forgotten that, before the eighteenth century, no efficient methods of surveying were available. Taxation of agricultural land entered a new phase of its history when these were improved. The *Censimento Milanese*, at the beginning of the eighteenth century was one of the first results.

[5] Sébastien le Prestre, Seigneur de Vauban (1633-1707), Maréchal de France and a favorite with Louis XIV (until that publication), had previously written a tremendous number of memoirs on fortifications, war, naval matters, public finance, religion, money, agriculture, and colonization that fill an imposing series of manuscript volumes. In 1698 he had instigated orders for a census of the population, and in 1695 he had first suggested the project that he published in 1707. Somewhat like Étienne Boileau

---

four centuries and a half before him, he had a passion for collecting and arranging economic facts and figures. Accordingly, he has had his partisans, who claimed for him the title of *Créateur de la Statistique* (E. Daire in his edition of the *Dixme royale*, in *Economistes-financiers du XVIII^{e} siecle*, 1843, which is the edition used). The *Dixme* has been translated into English. There is a bibliography of Vauban by F. Gazin (1933). Also see D. Halévy, *Vauban* (1923); J. B. M. Vignes, *Histoire des doctrines sur l'impôt en France* (1909); and F. K. Mann, *Der Marschall Vauban* . . . (1914).

In his effort to secure fiscal reform Vauban had two allies whose relation to him however is not clear. The one was Boisguillebert, who was much more of an economist than was Vauban and whose performance will be considered in chs. 4 and 6 of this Part. Here we need only record, first, that his proposal, though differing from Vauban's, was yet conceived in the same spirit and expressed the same economic and fiscal vision; and, second, that Boisguillebert's outspokenness or rather bitterness—witness the subtitle of his first book, *Le Détail de la France. La France ruinée sous le règne de Louis XIV*—and his inability to appreciate practical difficulties—witness another subtitle, *Moyens très-faciles* [!] *de faire recevoir au Roy 80 millions par-dessus la capitation, praticable par deux heures de travail des Messieurs les Ministres* [!!]—naturally annoyed the poor slaves whose bad luck it was to serve at that time as ministers of finance (Pontchartrain, Chamillart, Desmarets). The other ally therefore found it easier to get on terms with them. This was the Abbé de Saint-Pierre (1658-1743), famous as moralist, all-round reformer, sponsor of the League-of-Nations idea, whose considerable performance as a practical economist is gradually emerging into the light of day (*Ouvrajes*, 1733-41). See P. Harsin, 'L'Abbé de Saint-Pierre, économiste,' *Revue d'histoire économique et sociale* (1932).

[6] He has been called a forerunner of the physiocrats. There is not the slightest foundation for this. As has been pointed out before, concern with agricultural conditions does not make a writer a physiocrat.

the truth that a man can be an excellent economist without being a good theorist. The reverse also holds true, unfortunately.

The second work to be mentioned, Broggia's[7] treatise on taxation, is of an entirely different nature and has been selected for entirely different reasons. It also outlines an 'ideal' system of taxation that might have been derived by critically developing that of Vauban: the main practical ideas, barring one, are roughly similar. But Italian sources, both earlier and contemporaneous ones, can be indicated for every particular, among others for the 'canons of taxation' (ch. 1) that, further expanded in Verri's *Meditazioni* (1771), essentially anticipate those of A. Smith. Thus the freshness—the 'subjective' originality—that makes Vauban's *Projet* such delightful reading is lacking here. Nor is there anything to correspond to the chief merit of Vauban's work, the facts and figures. Instead, however, we find systematic completeness and more searching analysis: the result is—at least—a digest of all that was best, not only in the public-finance literature of the eighteenth century but also in most of that of the nineteenth. There is the fifteenth-century rationalization of taxes as payments for security and as equivalents for the services rendered by the government. There is the principle that direct and indirect taxation are necessary complements of each other, the two hands of finance (Gladstone might have said that: actually, he spoke of two sisters so nearly alike that one hesitates in deciding which one to court). A proportional tax (10 per cent) on *certain* incomes (*entrate certe*, mainly from land, houses, including owner-inhabited ones, and public funds: compare A. Smith's predilection for land and house taxes) that will not be transferred, is combined with a system of indirect taxes (*gabelle*) that are supposed to be transferred to buyers, whereas all *uncertain* incomes (profits, wages, and so on) are to be left free. The interesting thing about this is the underlying diagnosis of the economic situation: Broggia's finance was to foster the increase of wealth through industrial and commercial activity; for this purpose, acquired wealth was to be taxed to force people into business pursuits, whereas both wealth in the making and labor were to be touched gently. This is why he recommended that money loans to business or monetary business funds (money *impiegato a negozio*) be left untaxed, and why even his direct taxes were not on personal incomes but on 'real' or 'objective' returns—he did give weight to considerations of administrative convenience in this, as Bodin and Botero had done already, but the essential point was to avoid fettering business activity and oppressing 'struggling poverty.' There are three aspects to this: first, a scheme of aims and valuations with which we are not more concerned than we are with all his talk about 'justice'; second, a vision of social and economic conditions and their possibilities which went far below the surface; and, third, analysis, though not made entirely explicit, of economic causes and effects. It is this third point that constitutes the scientific merit of the work.[8]

---

[7] Carlo Antonio Broggia's (1683-1763) *Trattato de' tributi, delle monete e del governo politico della sanità* (treatise on taxes, money, and the policy of public health, 1743) was planned as a comprehensive textbook-like treatment of the three topics indicated in the title. The edition in the Custodi collection separated them and we are interested only in the first which forms a self-contained unit (though there was considerable merit also in Broggia's ideas on money and public health). We know almost nothing about the man—he seems to have been a businessman, or a retired businessman, of considerable acquirements. As a Neapolitan, he may be included in what we have called the Neapolitan school. The most interesting parts of the treatise on taxes are reprinted in the *Economisti Napoletani* of Tagliacozzo, who also presents us with a summary and appraisal of the work that contains references to immediate Italian predecessors of Broggia, especially Pascoli and Bandini—important links in the evolution of fiscal doctrine and analysis that must be neglected, to the fatal injury of the resulting picture, in a sketch like this. A fuller though, perhaps, not quite satisfactory picture both of Broggia's work and of the development in which it was an element may be found in G. Ricca-Salerno, *Storia delle dottrine finanziarie in Italia* (1881).

7. NOTE ON UTOPIAS

A few words will be inserted here on sixteenth- and seventeenth-century state novels (*Staatsromane*)[1] which derive their name—Utopias—from the title of the peak success of the genus, the *Utopia* of Thomas More. This meaning of the term Utopia must be distinguished from the meaning that the Marxist phrase Utopian Socialism is intended to convey. F. Engels (1892) defined 'utopian' in contrast to 'scientific' socialism to denote socialist ideas that are (a) unconnected with an actual mass movement and (b) not based upon any proof of the existence of observable economic forces that tend to realize those ideas. In this sense, Morelly's *Code de la Nature* (1755) is certainly utopian socialism. We have not called it a Utopia, however, not only because this would have restricted the concept to socialist utopias but also because in this book we wish to use the term, except when notice to the contrary is given, for something entirely different—for a distinctive literary type—for artistic creations of a nature that the term state novel suggests and Plato's *Republic* exemplifies. In this sense, description of the blueprint of a socialist or any other kind of society, even though it does not exist, like the one drawn by Morelly, is not a utopia. This type, which, no doubt under Greek influence, was fairly popular in the epoch under review,[2] is difficult to interpret. A literary form may enshrine anything—from a day dream cast into a prose poem to the most realistic analysis. Fortunately it is always possible to recognize the presence and especially the absence of the latter element, though it is not always possible to say whether what presents itself as a statement of fact or as an imperative is to be understood as 'poetry or as truth.' Only four instances need be mentioned, the works of Francis Bacon, Harrington, Campanella, and More. And the first three may be dismissed at once as irrelevant to our purpose: Bacon's *New Atlantis* (1627), a fragment—a singular deviation from the creed of 'inductive science' preached by its author—and Harrington's *Oceana* (1656) are of no interest at all; to Campanella's *Civitas solis* (City of the Sun, 1623) Platonic rays playing around rather commonplace matter do lend a glamour not its own;[3] but the case of More's *Utopia* is different.[4]

---

[8] Professor Luigi Einaudi credits the physiocrats with having 'created' the pure theory of taxation (*Atti, Reale Accademia delle Scienze di Torino*, 1931-2). But with due deference to Professor Einaudi's authority, I am inclined to think that in Broggia and the literature behind him there seem to be much more valuable elements of such a theory if, indeed, on the strength of the fact that neither he nor any other eighteenth-century writer produced a satisfactory analysis of incidence, we refuse to find in him that theory itself.

[1] [See explanation of *Staatsromane* in ch. 1, sec. 2 of this Part.]

[2] The reader presumably knows, however, that it has never died out, witness the great success of Bellamy's *Looking Backward, 2000-1887* (1888). But we shall have no occasion to mention any of these more modern Utopias in this book.

This rich book is full of mature wisdom and has naturally been the object of many different interpretations which, since we are concerned only with one of the many aspects it presents, and with a very minor one at that, we need not stay to discuss. Nor need we enter into More's social criticisms or the general features of his communist scheme of life that facilitates the solution of most economic problems by the postulate of simple and invariant tastes in a population that is kept stationary or almost stationary by regulated or rather enforced emigration—one of the many points of similarity with Plato's *Politeia*. Two things have relevance to analysis, however. First, the general plan of production and distribution of goods: tastes being given, the quantities currently produced, according to government regulations, by all adults except a privileged class of 'learned' men—not quite Plato's guardians, because there is an elected king—are distributed so as to put all districts on a footing of equality on the basis of statistics of current production and by means of a system of public storage. This, whatever else it may mean, is not a bad method to put into evidence the essentials of the functioning of *any* economic organism. In particular, a serviceable theory of money may be derived from this conception, and More hints at this theory by pouring out the vials of humorous wrath on the fetishism of gold and silver, which, unless required for paying for excess imports, Utopia uses only for purposes indicative of More's contempt. Criticism of the popular economics of his day may well have been one of the major aims of this construction. Second, his criticism of economic conditions, though most weighty in legal and especially penological matters, were interspersed with diagnoses and formulations some of which may be ranked as contributions to analysis. The tracing of unemployment to enclosures, though always a half truth, was not, in 1516, the commonplace it became soon afterwards. And he introduced the word and concept of oligopoly in exactly the same sense in which we use it now.

---

[3] Tomaso Campanella (1568-1639); in his preface to Plato's *Politeia*, Jowett presents an abstract. There is also a translation (in H. Morley's *Universal Library*). All works on state novels and most histories of socialist and communist ideas, as well as several monographs, deal with Campanella more or less fully.

[4] Sir Thomas More (1478-1535), the English Lord Chancellor who was beheaded by Henry VIII and canonized 400 years later, was a man of penetrating intelligence, comprehensive (classic) learning, and wide experience, none of which ever killed his good-natured humor; and all of these four qualities went into the making of his *Utopia*, published in Latin in 1516, translated into English (after German, Italian, and French translations had appeared) in 1551. The considerable literature on More, so far as a perfunctory examination permits me to judge, is for the most part not relevant to our purpose. Bonar's *Philosophy and Political Economy* will tell the interested reader all that has any bearing upon economics as such. Reference may, however, be made also to E. Dermenghem, *Thomas Morus et les utopistes de la renaissance* (1927).

CHAPTER 4

The Econometricians and Turgot[1]

1. POLITICAL ARITHMETICK 209
2. BOISGUILLEBERT AND CANTILLON 215
3. THE PHYSIOCRATS 223
    [(a) *Quesnay and the Disciples*] 223
    [(b) *Natural Law, Agriculture, Laissez-Faire, and l'Impôt Unique*] 228
    [(c) *Quesnay's Economic Analysis*] 232
    (d) *The Tableau Économique* 239
4. TURGOT 243

THE INDIVIDUALS and groups to be discussed in this chapter were also Consultant Administrators, though not of the academic type, and some of them qualify in addition as philosophers of natural law. Nevertheless, it was not only to relieve a chapter already overloaded with names that they have been reserved for separate treatment. Except for the great figure of Turgot, which is to come in at the end of the chapter, they have something in common that makes it desirable to marshal them into a connected array—the spirit of numerical analysis. They were Econometricians. In fact their works illustrate to perfection what Econometrics is and what Econometricians are trying to do.[2]

1. POLITICAL ARITHMETICK

Repeatedly we have had occasion to observe that, with economists of all types but especially with the Consultant Administrators, factual investigation was the primary task that absorbed most of the available manpower and progressed more satisfactorily than did such 'theory' as there was. This was so from the first, as such representative examples as Botero and Ortiz suffice to show. However, in the seventeenth and eighteenth centuries, a type of teaching developed, especially at the German universities, that specialized in purely descriptive presentation of the facts relevant to public administration. A German professor, Hermann Conring (1606-81), is usually credited with having been the first to give lectures of this kind. Another, Gottfried Achenwall (1719-72), who did the same, introduced the term Statistics. These 'statistics' did not present figures primarily but rather non-numerical facts, and therefore had nothing to do, in the hands of those professors, with what we now call statistical method. But the purpose of this information was much the same as that which our figures, treated by somewhat more refined methods, are calculated to serve. The definition of statistics adopted as late as 1838 by the Royal Statistical Society—to give it its present title—still turned upon 'illustration of the conditions and prospects of society,' and thus covered the work of Conring and Achenwall quite well.[1] But—alas for the academic profession!—the really interesting development did not start from it.

---

[1] [J. A. S. had originally entitled this chapter 'The Econometricians'; on the typescript he added 'and Turgot?' in pencil.]

[2] The word Econometrics is, I think, Professor Frisch's, and it has been coined by analogy with Biometrics, statistical biology. A distinctive name, embodying a program, is perfectly justified in this case (see the first number of *Econometrica*, January 1933, on the foundation and aims of the Econometric Society). And so we may leave it at that, though the term is exposed to objection on philological grounds: it ought to be either Ecometrics or Economometrics.

The decisive impulse came from a small English group led and inspired by Sir William Petty.[2] The nature both of what he called Political Arithmetick and of his personal contribution to it has been formulated with unsurpassable fairness by one of his ablest followers, Davenant[3] (*Of the Use of Political Arithmetick*, *Works*, I, p. 128): 'By Political Arithmetick we mean the art of reasoning by figures upon things relating to government. . . The art itself is undoubtedly very ancient. . . [But Petty] first gave it that name and brought it into rules and methods.' It will be seen that the 'methods'—which of course he did not invent either but, as it were, helped into consciousness—do not consist in replacing reasoning by the assembling of facts. Petty was no victim of the slogan: let facts speak for themselves. Petty was first and last a theorist. But he was one of those theorists for whom science is indeed measurement; who forge analytic tools that will work with numerical facts and heartily despise any others; whose generalizations are the joint products of figures and reasoning that are never allowed to part company. The relation of this procedure to that of the physical sciences—and to Newtonian principles, in particular—is so obvious as to make it necessary to emphasize that Petty displayed no propensity to borrow from them or even to strengthen his case by doubtful analogies with them. He simply proposed 'instead of using only comparative and superlative words and intellectual arguments . . . to express [himself] in terms of number, weight and measure.' No less obvious is it that he was acutely aware of the polemical aspects of his methodological creed. He was quite ready to fight for it and to start what would have been the first controversy on 'method.' But nobody attacked. A few followed. Many admired. And the vast majority very quickly forgot. That is to say, economists did not forget the name; they even remembered individual views of Petty's on various practical issues and some of his theories—precisely those that were couched in mere

---

[1] Since statistics came to mean sometimes various bodies of facts, and sometimes various types of methods, there is nothing surprising in the number of different definitions that have been proposed by different workers from their different standpoints. The German statistician Engel, whom we shall meet again on a more important occasion, once put that number as high as 180. See G. Loyo, *Evolución de la definición de estadística*, Publicación 44 of the Instituto Panamérico de Geografía e Historia (1939).

[2] Petty (1623-87) was a self-made man—physician, surgeon, mathematician, theoretical engineer, member of parliament, public servant, and businessman—one of those vital people who make a success of almost everything they touch, even of their failures. Though he paid the price of his versatility, his is one of the great names in the history of economics. But as regards his posthumous fame, luck lent its aid to merit. Marx's decree to the effect that Petty was the founder of economics added socialist applause to bourgeois eulogies initiated by Roscher in 1857. Thus, economists whom no other topic could unite, among them many who were complete strangers to the real meaning of Petty's message, have ever since joined forces in extolling him, Germans even more than Englishmen. Perusal of Lord E. Fitzmaurice's *Life* (1895) is recommended. Of Petty's writings the following are of prime importance for us: *A Treatise of Taxes and Contributions* (1662); *Verbum Sapienti* (written 1665, publ. 1691); *Political Anatomy of Ireland* (1672); *Political Arithmetick* (written 1676, publ. 1690); *Quantulumcunque concerning Money* (written 1682); *Essays on Political Arithmetick* (written 1671-87); all republished in *The Economic Writings of Sir William Petty*, by C. H. Hull (1899). This edition also contains the celebrated *Natural and Political Observations . . . upon the Bills of Mortality*, originally published (1662) by John Graunt. A long and inconclusive controversy has been waged on the question of Petty's share in this performance, which may be looked upon as the fountainhead of modern demography, though Graunt should not, on this account, be called the 'founder' of statistics. Lord E. Fitzmaurice's *Life* has been supplemented by the Marquis of Lansdowne's editions of the *Petty Papers* (1927) and of the *Petty-Southwell Correspondence, 1676-87* (1928).

[3] The name of Charles Davenant (1656-1714) moves slowly into the front-rank position that belongs to him but it has not quite arrived there as yet. He was a public servant but also a politician, thrice elected M.P., and, as such, a violent enemy of the Whigs rather than a violent Tory: perhaps it is this and the effects of this on some

---

of his writings that interfered with his recognition. There also was something else. Those historians who ask 'What does a man stand for?' did not quite know what to make of him. On the one hand, the 'liberals' among them were delighted when they hit upon such phrases as that trade is by nature free, that it finds its own channels, that laws which limit or regulate it are seldom advantageous to the public (though they may serve individual interests), and that money was a mere counter. On the other hand, they were grieved to find in him so much about regulative policy that they had to class him as an adherent of a (nonexisting) 'mercantilist theory.' Some accounted for what they took to be a self-contradictory attitude by the hypothesis that in those earlier writings in which the 'liberal' passages occur, Davenant spoke his mind freely whereas, later on, in office especially, he turned opportunist. We shall see later (below, ch. 7) that there is another explanation, viz., that he was a good economist. His *Works* have been (incompletely) edited by Sir Charles Whitworth (1771). Additional ones have since emerged, the latest find being published under the title *Two Manuscripts by Charles Davenant*, 1942 (*A Reprint of Economic Tracts*, ed. by Professor G. Heberton Evans, Jr., with an instructive introduction by Professor Usher). Also see Y. Ballière, *L'Oeuvre économique de Charles Davenant* (1913). His contributions to economic analysis amount to an impressive total and may be classified as follows: (1) there is, implicit but clear, behind all his writings the awareness of the logic of the relations by which things economic hang together, a merit that is somewhat, but not necessarily much, reduced by the priority of Child, Barbon, and also others; (2) he substantially improved, though only by what may be called a case method, his epoch's acquirements in the theories of money and of international trade and finance; (3) he was one of the first authorities of his time on public finance—taxes, debts, and so on; (4) he was one of the few who understood, and co-operated in, the work of Political Arithmetick. Individual points will be noticed in subsequent chapters.

slogans. It was the inspiring message, the suggestive program, which wilted in the wooden hands of the Scottish professor and was practically lost to most economists for 250 years: A. Smith took the safe side that was so congenial to him when he declared (*Wealth*, Book IV, ch. 5) that he placed not much faith in Political Arithmetick.

Not lost, however, was the impulse given to vital statistics and thus indirectly to statistics in general. In this, the chief or even sole merit is now usually attributed to Graunt (see footnote 2 above).

In the next chapter we shall touch upon the controversies of that period on the subject of the growth (or decline!) of population which until the census of 1801 was, in England at least, a matter of conjecture. This, however, was only one of the problems that Graunt's or Petty's achievement put into a more promising shape by means of the 'bills of mortality' drawn from parish registers. Computations of the chance of survival with application to insurance, of the influence of inoculation on longevity, of the relation of the sexes at birth, and of the average duration of marriage in relation to the ages of husband and wife are examples taken at random from a large field of research that was to be taken into cultivation within the subsequent hundred years on the lines chalked out by Graunt's book. Nor is his merit adequately characterized by calling him the 'Columbus of the mortality bills.' It is perhaps still more to his credit that he displayed a sense of the methodological nature of those mass phenomena that may be described by 'laws' although the individual elements of them are fortuitous. It must suffice to mention the main stepping stones of further progress. The first to inquire with exactness into the problem of chances of survival was E. Halley (*An Estimate of the Degrees of the Mortality of Mankind*, 1693). J. P. Süssmilch (*Die göttliche Ordnung in den Veränderungen des menschlichen Geschlechts* . . . , 1740) may be said to have put vital statistics definitely on its feet by developing and systematizing the work of his English predecessors. The theory of probability, the basis of statistical method, was developed by Jacques Bernoulli (1654-1705; *Ars conjectandi*, 1713) and still further by his nephews Nicholas (1687-1759) and Daniel Bernoulli (1700-1782), who also worked out further applications. In view of the close alliance between modern economics and not only the material but also the methods of statistics, it is highly regrettable that we cannot follow this line of advance any further. The reader may, however, glean most of what is wanting here from a study of H. L. Westergaard's excellent *Contributions to the History of Statistics* (1932).

More important for economics proper was another performance that illustrates the curious obtuseness (just lamented) of economists: Gregory King's (1648-1712) law of demand for wheat.[4] It refers to deviations from an assumed normal and states that if the harvest falls short of this normal by 1, 2, 3, 4, or 5-tenths, the price will rise above what we should call its trend value—which King, however, assumed to be constant, at least, for many years together—by 3, 8, 16, 28, or 45-tenths. From this an equation, explicitly giving the law of demand implied, can easily be derived.[5] The remarkable thing is that King, though he did not attempt any further refinements, evidently understood the problem perfectly; that he worked with deviations from a normal is a particularly interesting touch. Still more remarkable is it that, in spite of the general notoriety that 'King's law' was to gain, it did not occur to economists either to improve upon it—though all that was required was to proceed further on a line unmistakably chalked out—or to apply the same method to other commodities until the work of H. L. Moore, 1914 (see below, Part IV, chs. 5 and 7) released the avalanche of statistical demand curves of our own time—a lag of over 200 years. Do not let us forget, however, the econometric work done elsewhere, for example, in Italy, by such men as Verri or Carli.

---

[4] *Natural and Political Observations and Conclusions upon the State and Condition of England in 1696* (sec. VII). This work, a pioneer of quantitative economics and one of the best examples of what Political Arithmetick stood for, was not published by the author. Davenant incorporated some parts of it in his *Essay upon the Probable Methods of Making a People Gainers in the Ballance of Trade* (1699), but the whole was not presented to the public before 1804, when George Chalmers published it with a life of the author. The first five sections deal with the number of inhabitants, ingeniously inferred from hearth-tax returns, age distribution, marital status, mortality in cities and the country, and cognate matters. Sections VIII-XIII are devoted to matters

To return to Petty. All or most of his writings were prompted by the practical problems of his time and country—problems of taxation, of money, of the policy of international trade particularly with a view to getting the better of the Dutch, and so on. The superior quality of his mind shows in all his comments and suggestions, but there is nothing very striking or very original or very distinctive about them: they represented the views that were then current, or rapidly becoming current, among the best English economists. Nor is there anything distinctive in the fact itself that Petty no doubt reasoned from a more or less clearly perceived set of principles or theoretical schema; several of his contemporaries did that, and his schema was no more articulate than were theirs. There was something, however, that was specifically his own and in which his mental energy and theoretical talent asserted themselves conspicuously: as already observed, he hammered out concepts from, and in connection with, statistical investigations, and in doing so he got further at some points than did any of his contemporaries. His concept of velocity of money is—rightly—the most famous example and will be mentioned again in Chapter 6. Another example is his work on national income: he did not bother about its definition, but he recognized its analytic importance and he tried to figure it out. Modern income analysis may be said, in this sense, to start with him, though it seems on the whole better to trace it to Quesnay (see below, sec. 3). A third example is this: everyone knows the phrase that has been repeated *ad nauseam*, 'labor is the father . . . of wealth, as lands are

---

of public finance. From our standpoint, sections VI and VII are the most important. Besides the famous demand schedule, they contain other noteworthy contributions, such as his estimates of the income and expenditure of the nation in 1688, of meat consumption, and of the quantity of gold and silver in England and other countries.

[5] It has been calculated by G. U. Yule ('Crop Production and Prices: A Note on Gregory King's Law,' *Journal of the Royal Statistical Society*, 1915, p. 296 et seq.) at $y = -2.33x + 0.05x^2 - 0.00167x^3$.

the mother.' This means that he put on their feet the two 'original factors of production' of later theorists. Illogically dropping the mother, he declared elsewhere that capital (the 'wealth, stock, or provision of the nation') is the product of past labor—which brings to mind James Mill's blundering reformulation of Ricardo.[6] But it cannot be repeated too often that in themselves, and without the developments that make them valuable, such suggestions amount to very little. What does amount to something is his research on a 'natural par' between land and labor, that is to stay, his attempt, foreshadowing the much more thorough-going one of Cantillon, to relate the values of land and labor by equating a piece of land that will produce a 'day's food of an adult man' (with certain corrections) to the day's labor of such a man. If technological and all other conditions of production and consumption remained severely the same, this procedure might give us the economic philosopher's stone—the unit of measurement by which to reduce the available quantities of the two 'original factors,' land and labor, to a homogeneous quantity of 'productive power' that could be expressed by one figure, and the unit of which might serve as a land-labor standard of value. As it is, this interesting venture, like all similar ones, proved to be a blind alley.

Of course, this was no explanation of the phenomenon of value, still less a labor theory of value—if anything, it was a land theory of value. On division of labor, however, we find all the essentials of what Adam Smith was to say about it, including its dependence upon the size of markets. Pricing is dealt with sketchily. Contrary to Marxist opinion, there is no theory of wages (unless we choose to dignify by this name the proposition that laborers 'should' never get more than a subsistence minimum because if they got double as much they would reduce their work to half!) and no exploitation theory of surplus value or of rent (unless we choose to dignify by these names the trivial propositions that there would be no surplus if the laborers claimed the whole product, that the rent of land is what is left after costs of production have been defrayed, and that it increases as, with increasing demand, corn must be brought from greater distances).[7] There is, however, at least in a particular instance that is not too well framed, a perception of the tendency toward equalization of returns as between industries.[8] Although it lacks the reference to margins, which would be necessary to make the theorem tenable, we have here in fact a contribution toward the explanation of the business mechanism.

---

[6] See below, Part III, ch. 6.

[7] *Treatise of Taxes*, ch. 5. This 'discovery' of the rent of location zealous admirers may easily construe so as to imply decreasing returns and, in the end, the *whole* of the Ricardian theory. Only, this would be quite unhistorical.

[8] The argument, a rather interesting illustration of the ways of primitive analysis, is simply this: if, *by the same amount of labor*, one man produces corn and another man produces silver, then both will in general be left with some corn or silver after the usual deductions have been made (he also deducts the necessary consumption of the producers or, alternatively, assumes that the silver producer, besides producing silver, has also supplied himself with the means for that necessary consumption). Now Petty holds that the values of these two net returns must necessarily be equal and, since silver is the monetary metal, this equality determines the money price of corn, hence the monetary value of the corn 'rent.' As a useful exercise, the reader should work out precisely

Finally, Petty's theory of interest, so far as he can be said to have had one, points back to the scholastics. Direct influence is not quite impossible, since he received part of his education at the Jesuit college at Caen. There is, on the one hand, his statement that foreign exchange is 'local interest,' which suggests, though he does not say so quite explicitly, that he would have agreed to the phrasing that interest is 'exchange over time'—the scholastic doctors considered, though they did not accept, an explanation on this line. And there is, on the other hand, Petty's explicit statement to the effect that interest is a compensation 'for forbearing the use of your own money for a term of time agreed upon whatsoever need you may have of it meanwhile." This, especially if considered in the light of his disapproval of interest on money that the lender may claim at any time, is simply late scholastic doctrine. His various and not always felicitous considerations about the relation between interest and the rent of land—where he conspicuously failed to make an obvious contribution, namely, to derive the value of land by means of discounting its net return by the prevailing rate of interest—also recall scholastic arguments, although no outside influence need be invoked in order to understand why this problem should obtrude itself to any analyst.

2. Boisguillebert and Cantillon

Though, as a leader in the field of public finance, we have met Boisguillebert already and though, as a leader in the field of money, we shall meet him again before long, it is desirable not to miss him in the scenery we are trying to visualize now[1] as an important figure in the field of 'general theory.' He

---

why this argument is unsatisfactory and especially why it does not explain anything about the rent of land. This argument has sometimes been used in support of an attempt to credit Petty with a labor theory of value—the values of corn and silver being compared by means of the labor hours they embody. Our opinion on this matter will depend on the weight we are prepared to attribute to incidental use of such a standard of comparison. Petty's father and mother slogan does not point in this direction.

[1] Pierre le Pesant, Sieur de Boisguillebert (1646-1714), was a public-spirited member of the semi-hereditary civil-service gentry of prerevolutionary France (*noblesse de robe*) and lived mostly in Normandy removed from all the Paris influences that might have interfered with the originality of his ideas. Though, as we know, chiefly preoccupied with the problems of French fiscal policy and nearly as fact-minded as was Vauban, he differed from the latter not only in the much wider scope of his interests but also in the fact that he was theoretically articulate—perhaps more so than any writer before Cantillon. His chief works (*Le Détail de la France*; *Le Factum de la France*; *Traité de la nature, culture, commerce et intérêt des grains*; *Causes de la rareté de l'argent*; *Dissertation sur la nature des richesses, de l'argent et des tributs*) were re-edited, by Eugène Daire, in *Économistes financiers du XVIIIe siècle* (*Collection des principaux économistes*, publ. by Guillaumin, 1843). Daire's prefatory note to this edition, so far as I know, is the first document of that Boisguillebert cult, the manifestations of which contrast so curiously with (and are in fact only explainable by) the persistent neglect

has been called a precursor of the physiocrats, and it is easy to see why: on the one hand, he was an energetic sponsor of the agricultural interest; on the other hand, we find in his pages such phrases as: all that is necessary is *laissez faire la nature et la liberté*. But though these facts do suffice to put him into line with the political thought of the physiocrats, they do not suffice to make him the ancestor of specifically physiocrat analysis. There is analytic affinity between his and Quesnay's views on money (see below, ch. 6) but on the whole, it seems better not to stress the relation too much. He was one more of those authors who saw the economic organism as an equilibrium system of interdependent economic magnitudes and who constructed this system from the angle of consumption—getting further, perhaps, than anyone before Cantillon. His economic sociology turned, in an almost Marxist spirit, upon two social classes, rich and poor, the existence of which he explained in a way that was to become quite common as the eighteenth century wore on. The stronger individuals, by *crime et violence*, get hold of the means of production and then do not want to work any more; also—a very modern touch that the reader will not fail to appreciate—these strong robbers, who have become rich, tend to stock money rather than goods (*hoarded* money, the 'moloch of the world'!), and thereby depreciate real wealth and disturb the current of economic life. The economic principle of order he found in competition quite as clearly as did A. Smith more than half a century later. From the standpoint of analysis, this is decisive. That, on the strength of this, he did not (as did A. Smith) espouse unconditional free trade is immaterial, for into this practical conclusion enter so many other considerations and, in addition, so many personal preferences that its acceptance or rejection per se proves nothing for or against a man's analysis. But though his conception of competitive 'proportionate equilibrium' was as definite as A. Smith's, it was not more so: it did not occur to him to define it or to investigate its properties. Defining *richesse*, as Cantillon was to do, as the *jouissance* of everything that can give satisfaction (*plaisir*), he declared, as had Petty, that this wealth had no other sources

---

of Boisguillebert's performance by the vast majority of economists. Daire considered him to be the first in the 'learned chain,' the further links of which are Quesnay, Smith, Ricardo, and Rossi (!); Boisguillebert was the Columbus *du monde économique*, and so on and so forth. In a more reasonable manner, this cult was revived by Professor H. W. C. Bordewijk in his excellent *Theoretisch-historische Inleidingtot de Economie* (1931). But Miss Roberts, in an otherwise very meritorious book (*Boisguilbert: Economist of the Reign of Louis XIV*, 1935), displays a bad case of what Lord Macaulay called the illness of biographers or lues Boswelliana. It was, however, a rebuke administered to me by Professor A. Gray in a review of Miss Roberts' book (*Economic History*, 1937) for not having, in an old essay of mine, paid due respect to Boisguillebert that sent me back to Boisguillebert's writings and in fact changed my own opinion of him. Also, see F. Cadet, *Pierre de Boisguilbert, précurseur des économistes* [i.e. of the physiocrats] (1870); A. Talbot, *Les Théories de Boisguilbert et leur place dans l'histoire des doctrines économiques* (1903); R. Durand, *Essai sur les théories monétaires de Pierre de Boisguilbert* [which is, perhaps, the more correct spelling] (1922).

but land and labor,[2] and then simply went on to say that the process of incessant transformation of land and labor into consumers' goods will normally function without hitches if all commodities and services are produced on the unfettered initiative of competing producers—as if this did not require any proof. The first to attempt a (primitive) mathematical definition of equilibrium and a (also primitive) mathematical proof of that proposition was Isnard, who has as yet to conquer the position in the history of economic theory that is due him[3] as a precursor of Léon Walras.

Cantillon's great work[4] fared better both because of its well-rounded systematic or even didactic form and because it had the good fortune to gain, long before its actual publication (see footnote 4), the enthusiastic approval and the effective support of two very influential men, Gournay and Mirabeau. What Petty failed to accomplish—but for what he had offered almost all the essential ideas—lies accomplished before us in Cantillon's *Essai*. True, it was not accomplished in the style of a pupil who at every step looks back over his shoulder for the master's guidance, but in the style of an intellectual peer who strides along confidently according to his own lights. Likewise, Quesnay strode on according to his own lights and was no more a mere pupil of Cantillon than Cantillon was of Petty. Nevertheless, few sequences in the history of economic analysis are so important for us to see, to understand, and to fix in our minds, as is the sequence: Petty-Cantillon-Quesnay. Cantillon's econometric zeal derived its direction from Petty. The supplement to his *Essai* which contained his computations has unfortunately been lost. But, as we shall presently see, the results presented in its text suffice to show that it was Petty's problems—mainly the 'par' between land and labor—and Petty's methods which inspired them. Moreover, dependence or possible dependence—there can be no certainty about it—extends beyond such important individual points as the theory of velocity of circulation or the theory of population to the fundamental features of the general theoretical set-up. Exactly the same conclusion will be seen to apply to the relation of Quesnay's work to Cantillon's. Affinity is obvious, differences being not less revelatory of it than are agreements: for a man may learn from another by criticizing him just as well as by accepting his teaching, and some of Quesnay's views look indeed as if they had been derived from Cantillon by the former method. And, again, it is precisely the fundamental features of Quesnay's analytic set-up that are unmistakably foreshadowed in Cantillon's work. An analogy may be helpful: Cantillon was to Quesnay, and Petty was to Cantillon, what Ricardo was to Marx. This leaves out Boisguillebert, though there are important affinities between him and Cantillon and, as regards money, between him and Quesnay. But just now it seems important to focus the reader's attention on one strong and simple line of development. The only way to raise all this above vague generalities is to take a bird's-eye view of Cantillon's work or, to phrase it differently, to present a Readers' Guide. This is what I proceed to do.

---

[2] Petty, nevertheless, considered capital as accumulated labor. Boisguillebert's set-up, however, is an early case of the 'resolution' of produced means of production into services of natural agents and labor that was to be a central feature of Böhm-Bawerk's theoretical scheme (see below, Part IV, ch. 6), but Boisguillebert did not try to exploit this conception analytically.

[3] Achille Nicolas Isnard, an engineer about whom practically nothing is known, not even the exact dates of his birth and death, and who does not rate an article in the *Encyclopaedia of the Social Sciences*, wrote, besides another work that does not concern us, a *Traité des richesses* (1781) that seems to have been rescued from oblivion by a lucky chance: Jevons included it in his list of writings on mathematical economics that he appended to his *Theory of Political Economy*. The (almost) complete neglect of Isnard's work is understandable, however, because the historic performance mentioned in the text is embedded in a conventional argument against physiocrat doctrines and other neither very original nor very interesting matter. Owing to the weakness in our field of the specifically scientific interest, progress on this fundamental line was almost unbelievably slow.

[4] Richard Cantillon (the date of his birth is uncertain, but is usually given as 1680; he died, presumably murdered, in 1734) was a Paris banker of Irish extraction. He influenced French economists much more than English ones. He was indeed plagiarized by some Englishmen and recognized by others, among the latter being A. Smith. But he had to be practically rediscovered by W. S. Jevons ('Richard Cantillon and the Nationality of Political Economy,' *Contemporary Review*, 1881), whereas in France he was never quite lost sight of. Thus, his influence is obvious in Canard's *Principes d'économie politique* (1801), which, with apologies to the *Académie* that 'crowned' it—the same *Académie* that ignored Cournot and Walras—we shall only briefly mention again. On these grounds I class him as French, but I admit that anyone interested in such questions as the 'nationality' of a science can make out a strong case for claiming this Irish Frenchman as an English economist because of his descent from Petty. The *Essai sur la nature du commerce en général* is supposed to have been written about 1730 and was, though in a very unconventional sense, 'published' soon after; that is to say, the manuscript circulated and exerted influence soon after. (This meant a lot in a small and highly concentrated professional circle.) The date of its actual (posthumous) publication, 1755, therefore has not the usual significance; there is a Harvard University reprint (1892) and an English trans. under the auspices of the Royal Economic Society (1932). See H. Higgs, 'Richard Cantillon,' *Economic Journal*, June 1891. I do not know of any other good study on our author unless it be the very useful article in *Palgrave's Dictionary*. Jevons' estimate fails by overstatement. In particular nothing could be more infelicitous than to call the *Essai* the 'cradle' of Economics: this is precisely what it was not. There is a brief 'Biographical Note on Richard Cantillon' in the *Economic Journal*, April 1944, by Joseph Hone.

> The First Part contains the fundamentals of the analytic structure. In the first chapter we get the general layout by means of the key concepts—land, labor, and wealth. Exactly as with Petty, and just as misleadingly, land, the source of material, and labor, the form-giving or productive agent, enter on equal terms to turn out wealth which *n'est autre chose que la nourriture, les commodités et les agrémens de la vie* (Boisguillebert's definition). Chapters 2-6 present what to all intents and purposes is an economic sociology. We get first a theory of social classes: ownership of land—itself based upon conquest and violence as with Boisguillebert—creates the three fundamental 'natural' classes of landlords, farmers, and laborers (traders and entrepreneurs do come in, along with artists, robbers,

lawyers, beggars; but they are added to this schema, not really fitted into it). Then we get a very interesting theory of the origin of villages, the emergence of townships (Cantillon adopted a 'market theory' of towns, the theory that makes them develop first from periodical, then from permanent markets), cities, and capital cities. Besides creating the form in which many a nineteenth-century textbook was cast (in a sense even Alfred Marshall's treatise), Cantillon thus clearly proved his awareness of the fact, which smaller minds so often failed to grasp, namely, that the problems of any analytic social science necessarily divide up into two methodologically different groups: the group that centers in the question how the actual behavior of people produces the social phenomena we observe, and the group that centers in the question how that behavior came to be what it is. In Chapter 3 we also learn something about location—this is perhaps the first attempt (if we neglect embryonic considerations in the agricultural literature) at making some headway in this field.

Transition to pure economics—the economics that deals with behavior within the social framework described—is effected in Chapters 7-9 where Cantillon, for future reference, settles a number of preliminary questions concerning (a) differences in remuneration as between laborers and artisans and as between artisans in different employments, and (b) population. The former subject was to be a favorite with later writers, particularly A. Smith, and became a standard topic in the standard text of the nineteenth century. The latter subject will have to be dealt with in the chapter on population, wages and employment which follows. But it is just as well to record here, by anticipation, that Cantillon (clearly developing views of Petty) lets population, on the one hand, adapt itself to the demand for labor and, on the other hand, be regulated by a law of minimum-of-existence wages, so that his authority might be claimed for a Malthusian view were it not for the fact that he also (in this still more like Petty) looked upon labor as the 'natural riches' of a nation (ch. 16). This last points in a different direction, though there is really no contradiction between the two ideas. Both had become common doctrine in the seventeenth century.

Having thus prepared the ground, our author presents (ch. 10) a cost theory of normal price or value (*valeur intrinsèque*: never mind the objectionable word, it is quite harmless). This, if anything, falls short of the theory of the scholastics except that Cantillon, going through with Petty's theory, defined his cost in terms of the quantities of land and labor which enter into the production of each commodity. The obvious problem thus raised—we might call it Petty's problem—which Ricardo tried to dodge by eliminating land (see below, Part III, ch. 6) so as to be left with one factor only, Cantillon tackles in Chapter 11 by the alternative expedient: labor is reduced to land by the consideration that the labor *du plus vil Esclave adulte vaut au moins . . . la quantité de terre* that must be employed to provide for his needs. Or, rather, since according to Halley's tables about half the children died before reaching the age of 17 (and also for other reasons) it was roughly double that quantity. Other laborers get more than the *plus vil Esclave*, but this is either because their labor costs more land to produce or because their remuneration is subject to risk. The figures on workmen's budgets that Cantillon held to justify this estimate were in the lost supplement, but we must in any case credit Cantillon with having made the first important step in this particular field of research that was to develop considerably before the century was over. For the rest, it is not necessary to enter here into criticism either of the land-labor theory of value itself (if such it may be called) or of the particular attempt to make it numerically operative. As far as this goes, it must suffice to say that the latter is not what it seems to be, that is, complete nonsense, and that success on this line is not out of the question at some distant future. Let us repeat, however, first, that the really important thing is the message of econometric research that comes to us from this attempt—the message that *numerical* calculations must be at the basis of any science, however 'theoretical,' that is quantitative by nature; and, second, that the *arpents* of land per year (1 arpent = 330 sq. ft.) played exactly the same role in Cantillon's analysis that days of labor played in Ricardo's. And let us add that we have here the positive kernel of Quesnay's theory of normal value: his philosophies about the value-creating powers of nature added as little to the operative content of the Petty-Cantillon theory as Marx's philosophies about the value-creating power of labor added to the operative content of the Ricardo theory.

With the deviations of actual prices from this norm—that he reduced from cost in terms of land and labor to cost in terms of land alone—Cantillon dealt very carefully. There is nothing in the *Essai* that could rank as a theory of monopoly, which is the more serious because, as will be evident from the rest of our narrative, Cantillon reasoned on the hypothesis of the most perfect of perfect competitions so that any imperfections in it naturally acquire particular importance. But there is a lot about temporary deviations because of other reasons, that is, Cantillon paid much attention to the problem of market price as distinguished from normal price—exactly as did A. Smith later on. One feature of his treatment is worth noting because it persisted practically to J. S. Mill. Like all 'classics' of the nineteenth century, Ricardo especially, Cantillon never asked the question *how* market price is related to normal price and precisely *how* the latter emerges—if indeed it does emerge—from the supply and demand mechanism that produces the former. Taking this relation for granted, he was led to treat market price as a separate phenomenon *and to restrict the supply and demand explanation to it*. Thus emerged the superficial and, as the later development of the theory of value was to show, misleading formula—normal price is determined by cost, market price is determined by supply and demand—of which we shall see more in Part III.

Going on, we see Quesnay's figure still more clearly looming in the future, and Boisguillebert's no less clearly looming in the past. All the classes (*ordres*) of society and all the men in a state subsist or enrich themselves at the expense of the landowners (ch. 12). In the light of Chapter 14, this will be seen to mean no more than that, whereas every other income item is being balanced by a cost item, including in costs the necessary living expenses of the receiver, the landowners' rent is the only one that is not so balanced because, to use a later phrase, it is a return to a 'costless,' that is, non-produced, natural factor. Therefore, income from land, not being bound to certain more or less predetermined uses, can be spent in any way that the whims of the landowners may suggest. Its expenditure is the undetermined and, precisely because of this, the determining and active factor in the total of national consumption—hence also in the total of national production, so that everyone's economic fate depends upon *les humeurs, les modes et les façons de vivre* of the prince and the landowning aristocracy. These *humeurs* determine *les usages auxquels on emploie les terres,* and, in particular, how many people will be employed and able to make a living in a country (ch. 15), and how its balance of trade will look if both sides of it are measured in terms of land—which is the criterion he applied for judging the advantage or disadvantage a country derives from foreign trade. Not all of this reappears in physiocrat writings, not, for example, the last-mentioned point. But most of it does, and it is therefore desirable to make it quite clear what we are to think of it. Several aspects must be distinguished. First there is the theorem that pure rent is a net return that is explained by the productivity of scarce natural agents: this is a true and valuable proposition to which, after many wanderings, theory returned about 1870. Second, there is the statement that this net return is the only one, and that it is therefore agriculture which produces the whole net income of society, no other economic activity producing any of it. This, on the face of it, is wrong but—like the labor theory of value—it can be made true by the introduction of a sufficient number of auxiliary assumptions or postulates—such as absolutely perfect competition, stationary state, absence of urban rent, minimum-of-existence wages so that labor becomes a product of what the laborer consumes, and others[5]—which, however, destroy the statement's practical value. Third, there is the emphasis upon the importance of this net income's being promptly spent in order to keep the economic process going. This point played a small role with Cantillon but more with Boisguillebert before him and with Quesnay after him. And fourth, there is the emphasis—that is specifically Cantillon's—upon the way in which the net income is spent. A common-sense case can obviously be made out for this, especially for the society that stood before Cantillon's eyes.

Now, the *produit de la terre* is, so Cantillon asserted, divided into three approximately equal parts (*les trois rentes*), one-third replacing the farmer's outlays, including his own necessary keep, another third going to him as 'profits,' and the last third to the *seigneurs*. These landlords spend the equivalent of their third of the product of land in the towns where approximately half of the total population is supposed to live. The farmers also spend something on the manufactures produced in the towns, namely, one-fourth of their two-thirds. Thus, the equivalent of one-half (⅓ + ⅙) of the total product of agriculture finds its way to the towns, into the hands of the *marchands et entrepreneurs*, who expend it in turn on foodstuffs and raw materials and so on. Interpretation of this schema, for which Cantillon himself claims no more than the value of a very rough thumb-nail sketch, presents various difficulties into which we cannot enter. But it also presents many points of interest, of which we shall mention two.

---

[5] The reader will derive benefit from working them out fully.

First, Cantillon had a clear conception of the function of the entrepreneur (ch. 13). It was quite general, but he analyzed it with particular care for the case of the farmer. The farmer pays out contractual incomes, which are therefore 'certain,' to landlords and laborers; he sells at prices that are 'uncertain.' So do drapers and other 'merchants': they all commit themselves to certain payments in expectation of uncertain receipts and are therefore essentially risk-bearing directors of production and trade, competition tending to reduce their remuneration to the normal value of their services. This, of course, is scholastic doctrine. But nobody before Cantillon had formulated it so fully. And it may be due to him that French economists, unlike the English, never lost sight of the entrepreneurial function and its central importance. Though presumably Cantillon had never heard of Molina and though there is nothing to show that he actually influenced J. B. Say, it is none the less true that 'objectively' his performance on this point—and this was not suggested by Petty nor developed by Quesnay—is the link between those two. Second, if we look once more at Cantillon's sequence of payments and deliveries, which starts from the tripartite division of the gross product or revenue of farming—the *trois rentes*—and, through a number of definite stations, takes us back again to its starting point, the farmers, we immediately feel that we are beholding something that is novel, something that is not explicitly present in the schemes of Cantillon's predecessors or contemporaries—not even in Petty's—or in fact in the schemes of most theorists of any time. From them, we get indeed statements of general principles that govern the economic process. But they leave it to us to visualize this process itself as it runs its course between social groups or classes. Cantillon was the first to make this circular flow concrete and explicit, to give us a bird's-eye view of economic life. In other words, he was the first to draw a *tableau économique*. And, barring differences that hardly affect essentials, this *tableau* is the same as Quesnay's, though Cantillon did not actually condense it into a table. Cantillon's priority is thus beyond question as regards the 'invention' that Mirabeau, indulging as usual his generous ardors, compared in importance to the 'invention' of writing. But since Quesnay's formulation is so much more famous we shall add what there is to add in connection with his work.

It stands to reason that the *tableau* method offers special opportunities for investigating monetary phenomena, especially velocity of circulation—this is one of its chief advantages. In fact, Cantillon is at his best in this field. Chapter 17 of Part I, which presents the fundamentals of monetary theory, is not particularly original: we get pretty much the old stuff, including the divisibility, portability, et cetera, of gold and silver that recommend them for the monetary function. But the whole of Part II (which, however, also includes the theories of barter, market price, and so on) is devoted to money, credit, and interest, and so is much of Part III (mainly on foreign trade), where we find Cantillon's analysis of banks, bank credit, and coinage. Consideration of the main items of this brilliant performance, which in most respects stood unsurpassed for about a century—the automatic mechanism that distributes the monetary metals internationally is, for example, almost faultlessly described, an achievement usually credited to Hume—will however be reserved for subsequent chapters.[6]

3. THE PHYSIOCRATS

[(a) *Quesnay and the Disciples.*] The small group of French economists and political philosophers who were known in their own day as *Les économistes* and are known to the history of economics as Physiocrats presents strongly characteristic features to even the most perfunctory backward glance. But, when seen from our standpoint, the group really reduces to one man, Quesnay, to whom all economists look up as one of the greatest figures of their science. I know of no exception, though there are no doubt some differences in the reasons which different people would proffer in motivation of their individual agreement with the unanimous vote. Of the other members of the group we need to notice only Mirabeau, Mercier de la Rivière, Le Trosne, Baudeau, and Dupont. They were all of them disciples, nay, pupils of Quesnay in the strictest and most meaningful sense these terms will bear—disciples who absorbed and accepted the master's teaching with a fidelity for which there are but two analogues in the whole history of economics: the fidelity of the orthodox Marxists to the message of Marx and the fidelity of the orthodox Keynesians to the message of Keynes. They were a school by virtue of doctrinal and personal bonds, and always acted as a group, praising one another, fighting one another's fights, each member taking his share in group propaganda. They would in fact illustrate the nature of that sociological phenomenon to perfection had they not been something more than a scientific school: they formed a group united by what amounted to a creed; they were indeed what they had been called so often, a Sect. This fact naturally impaired their influence upon every economist, French or foreign, who was not prepared to take the vows to One Master and One Doctrine: moreover, it invited wholesale rejection of their teaching even by people who agreed with them on many points of theory as well as of policy or even by people who were under obligation to them. Some serious foreign scholars, particularly the leading Italians—among them Genovesi, Beccaria, and Verri—were indeed friendly. But so far as analysis and not policy is concerned, this friendliness meant little more than occasional lip service to specifically physiocrat tenets and should not mislead us into calling them physiocrats. Enthusiastic adherents of any importance are to be found in Germany only: it will suffice to mention the Margrave of Baden, Schlettwein, Mauvillon, and the Swiss, Herrenschwand. The necessary minimum of facts about the men so far mentioned is assembled below.

---

[6] A. Marshall (*Principles*, p. 55, n. 1) states that Cantillon was in important respects anticipated by Barbon (see below, ch. 7). Unless this refers to a certain (but not at all close) similarity between Cantillon's and Barbon's views on foreign trade—which both of them had in common with many other writers—I fail to see what Marshall can have meant.

François Quesnay (1694-1774), the son of a moderately successful lawyer, was above all else a surgeon-physician. His distinguished professional career absorbed the bulk of his energy and never left more of it for economics than a man may be able to reserve for a passionately beloved hobby. He wrote a medical treatise on bleeding, became General Secretary of the Academy of Surgery and editor of its journal, surgeon and eventually first physician to the king. Actually, he was medical adviser to Mme de Pompadour, in whom he found a protectress who was not only extremely kind but also intelligently understanding, a fact that assured to him a strategic position in the intellectual life of Versailles and Paris and should assure to the lady the lasting gratitude of economists. He was pedantic and doctrinaire to a degree and must have been an awful bore. But he had all the force of character that often goes with pedantry. It is pleasant to add that he was also thoroughly upright and honest. His loyalty to his protectress and his imperviousness to the typical temptations of his environment are amply established by an anecdote related by Marmontel that is more amusing than proper. The fact that he was the only creative force in his circle is somewhat obscured by his inability or unwillingness to work out his ideas fully and systematically. We will notice of his economic writings (his only voluminous work was the *Essai physique sur l'économie animale*, 1736) the *Encyclopédie* articles 'Fermiers' (1756), 'Grains' (1757), 'Hommes' (1757); the *Tableau économique* (1758; see below, sub d); the article 'Droit naturel' (1765) and the dialogue 'Du Commerce' (1766), both in the *Journal de l'agriculture, du commerce et des finances*; also the article 'Despotisme de la Chine' (*Éphémérides*, 1767), which has given rise to speculations on the subject of Chinese influence upon the physiocrats. (See, e.g., the article under this title by L. A. Maverick, *Economic History, Supplement to the Economic Journal*, February 1938.) Finally, there are Quesnay's *Maximes*, a highly revealing supplement to, or political commentary on, the *Tableau*

(1758), and the *Oeuvres économiques et philosophiques* edited by August Oncken with an interesting introduction (1888). All histories of economics deal with Quesnay, of course, the treatment in Gide and Rist calling for special notice. See H. Higgs, *The Physiocrats* (1897); G. Schelle, *Le Docteur Quesnay* (1907); G. Weulersse, *Le Mouvement physiocratique en France de 1756 à 1770* (1910), and *Les Physiocrates* (1931); M. Beer's *Inquiry into Physiocracy* (1939) is, quite rightly, almost entirely devoted to Quesnay himself.

Mirabeau we have met already (see above, ch. 3). After his conversion by Quesnay he devoted himself wholeheartedly to the cause of physiocracy, without however completely surrendering independent judgment. Two of his works already mentioned, the *Théorie de l'impôt* and the *Philosophie rurale*, may have been written in collaboration or consultation with Quesnay but are certainly not pure Quesnayism and contain things of which Quesnay cannot have approved. Nevertheless, the *Philosophie* (1763) was generally accepted as the first of the four textbooks of physiocrat orthodoxy. The sixth Part of *L'Ami* presented among other things Mirabeau's explanation of the *Tableau*.

Pierre-Paul Mercier de la Rivière (also known as Lemercier; 1720-93), whose impulsiveness or bad manners made him more conspicuous than he deserved to be, was responsible for the second of those textbooks, namely, *L'Ordre naturel et essentiel des sociétés politiques* (1767, reprint with useful introduction by E. Depitre, 1909), which Dupont de Nemours republished, in abstract, with a title that is revelatory of the group's frame of mind: it read *De l'origine et des progrès d'une science nouvelle* (1768). The first thirty-five chapters of Mercier's work are devoted to topics of political theory, which was what primarily interested him—Quesnay's scheme of *despotisme légal* that was really no despotism at all. The economics that occupies the remaining nine chapters is negligible. Both Diderot and A. Smith, however, thought highly of the book.

G. F. Le Trosne (1728-80) was a much abler man. But he was a lawyer and mainly interested in the natural-law aspects of the physiocrat system. In the field of economics he embraced physiocrat orthodoxy with some reservations. His *Liberté du commerce des grains* (1765) and his *De l'interêt social* . . . , second volume of *De l'ordre social* (1777), are meritorious performances, though they are not more than that.

The Abbé Nicolas Baudeau (1730-92) began as an enemy but had his day of Damascus in 1766 and from then on proved a most useful popularizer and controversialist as well as an efficient editor. His *Première introduction* . . . (1771; reprint with instructive introduction by A. Dubois, 1910) is the third of the group's textbooks, perhaps the weakest of all.

The fourth and best of these textbooks was the short *Abrégé des principes de l'économie politique* (publ. first in vol. 1 of the *Éphémérides*, for 1772) by Karl Friedrich von Baden-Durlach.

Pierre S. Dupont de Nemours (1739-1817), who entered adult life as an all-round literary free lance, was by far the ablest of the lot. Napoleon I once described Marshal Villars as a 'fanfaron d'honneur.' Similarly we can describe Dupont as a 'go-getter' who never forgot honor and principle and who, in particular, retained both a genuine interest in purely scientific questions and loyalty to the physiocrat creed throughout a career that offered every excuse for dropping them. He was won over to the cause of physiocracy by shrewd old Quesnay himself, who knew perfectly with whom he was dealing and never pulled the curb too sharply. Dupont immediately began to write copiously and effectively, publishing, among other things, a free-trade tract on grain exports and imports, 1764. On the strength of his success as a writer and editor, he secured various important employments under Turgot and later on under the last great minister of the *ancien régime*, Vergennes. We need not follow him through the ups and downs of life which, through the *Constituante* and the *Directoire* finally landed him—a Roman would say, with the loss of his shield—in the United States. Nor need we record his numerous publications, all of which bear witness to the brilliance of his talents, though these talents were those of the pianist and not those of the composer. The interested reader finds all except his letters in G. Schelle's *Dupont de Nemours et l'école physiocratique* (1888); also see Weulersse's work previously quoted.

As already mentioned, the school was thoroughly alive to the importance of propaganda and some of its members, Baudeau and Dupont especially, were very good at it. They founded discussion groups, worked upon individuals and agencies in key positions (the *parlements* especially), and produced a large quantity of popular and controversial literature. Their exploits in economic journalism, however interesting in themselves, would not have to be mentioned here were it not for the fact that, rising above it, they also produced the bulk of the material that went into the pages of the first scientific periodicals in the history of economics. The *Journal Oeconomique* (1751-72) had from the first kept a highly creditable level, rendering such services to scientific economics as the publication of translations of Hume (an important fact to keep in mind) and Josiah Tucker. The *Journal d'agriculture, du commerce et des finances* (1764-83) was intended from the first to supplement the *Gazette* by taking care of 'heavier' articles. The physiocrats partly controlled, partly had ready access to, this journal in 1765-6 and 1774-83. In 1765, however, Baudeau founded the famous *Ephémérides du citoyen* ('the citizen's daily records' would render this title, though it was a weekly), which, after Baudeau's conversion (from protectionism) in 1766 became identified with physiocracy. In 1768 Dupont took over. It was suppressed, owing to its strong hostility to the policy of the Aiguillon-Maupeou-Terray government, but recalled to life by Turgot (1774), whose policies it of course supported and some of whose enemies it attacked. The *Nouvelles éphémérides* died in 1776, and several efforts at resuming publication ended speedily in failure. But in a sense the short-lived *Journal d'économie publique, de morale et de politique* (founded 1796), though neither physiocrat nor the equal of the physiocrat journal, was the same kind of thing—as was in fact the later *Journal des économistes*. In more than one respect, therefore, the *Éphémérides* should be remembered by the student of the history of economics as one of the major achievements of Quesnay and his group. The reader will find an excellent sketch of this journal's career, giving all the essential facts in a short compass, in Palgrave's *Dictionary of Political Economy*, article 'Éphémérides' by Professor S. Bauer. I. Iselin founded a German replica, not equal to the prototype (*Ephemeriden der Menschheit*, 1776-82).

The impressions a reader gets as he wades through the volumes of the *Éphémérides* (I have been able to do so only to 1772) will of course vary from one reader to another. Personally, I have been greatly struck by a certain similarity they display to the scientific journals of late nineteenth-century Marxist orthodoxy, especially the *Neue Zeit:* the same fervor of conviction, similar controversial talent, quite the same inability to take any other but the orthodox view of anything, comparable capacity for bitter resentment, and equal absence of self-criticism. This shows particularly in the review articles. But solid merit all but obliterates these blemishes. Even apart from Turgot's *Réflexions*, which are, of course, in a class by themselves, and the explanations of the *Tableau*, there is a lot of thoroughly good stuff. Dupont, for example, contributed what is to my knowledge the first genuine history of economics. Masses of historical material are presented. Contemporaneous events from all corners of the globe are currently reviewed, though always from a narrowly sectarian point of view. All in all, the first of the long series of scientific journals of economics set a high standard for a long time to come. Its international success was well deserved.

The three Germans mentioned above need not detain us long. As regards the Margrave of Baden-Durlach (later Grand Duke of Baden, 1728-1811), who politically was one of the ablest public men of his time, we need add only a reference to his correspondence with Mirabeau and Dupont (edited, with introduction by K. Knies, 1892), which will repay perusal. J. A. Schlettwein (1731-1802) was the Margrave's executive collaborator in the experiment on the practical application of the physiocrat recipe to the village of Dietling which he reported in *Les moyens d'arrêter la misère publique* . . . (1772). Neglecting his later and fuller account of this experiment, we shall be content to mention his *Grundfeste der Staaten oder die politische Oekonomie* (1778). His almost turbulent activity in the service of physiocracy, considered as a practical scheme of agrarian reform, made a stir wherever he went and secured him one of those traditional positions in the history of scientific economics for which no analysis of published performance can unearth a justification. In one respect only can this man interest us, excellent though he no doubt was in his way. He illustrates to perfection the type of economist who will, I fear, never die out and who will forever discredit economics in the eyes of men whose approval is worth having. This is the type that says: here is the patent medicine that will cure all ills, 'the most important thing for the public' (these words are the title of one of his publications); in fact, the only thing that is important for humanity, is to swallow it. Jakob Mauvillon (1743-94) was a still more excellent man in many respects, but still weaker as an economist. His essay on luxury included in his *Sammlung von Aufsätzen* . . . (1776-7) is negligible. His *Physiokratische Briefe an den Herrn Professor Dohm* (1780) is in or near the center of a German controversy on physiocracy, for the sake of which alone this publication deserves to be mentioned. But this controversy itself needs to be mentioned only because some interest attaches to the fact that the physiocrat doctrine, though very little understood in its true scientific importance and mainly discussed in its practical aspects, could raise a full-dress debate around 1780. However we use the opportunity to refer to the best performance on behalf of physiocracy, K. G. Fürstenau's *Apologie des physiokratischen Systems* (1779). Of opponents it will suffice to mention C. K. W. von Dohm (*Kurze Vorstellung des physiokratischen Systems*, 1778) and J. F. von Pfeiffer (*Antiphysiokrat*, 1780). The latter's voluminous systematic works of the Justi type, no doubt marked by strong practical sense, have earned for him high praise from several historians. Jean (Johann) Herrenschwand (1728-1811), was a late physiocrat. Perhaps he should not be called a physiocrat at all, for he was not orthodox. But he was an able economist. His chief works were *De l'économie politique moderne* (1786); *De l'économie politique et morale de l'espèce humaine* (1796); *Du vrai principe actif de l'économie politique* (1797). There is a German monograph: A. Jöhr, *Jean Herrenschwand* (1901).

A sect with a creed and a political program naturally presents many aspects and calls for interpretative analysis from many standpoints other than ours: we shall first glance at some of these, then consider the bare bones of Quesnay's economic analysis, and especially the *Tableau économique*.

[(b) *Natural Law, Agriculture, Laissez-Faire, and l'Impôt Unique.*] Physiocracy[1] was nonexistent in 1750. *Tout Paris* and still more Versailles talked about it from 1760 to 1770. Practically everybody (excluding professed economists) had forgotten it by 1780. This meteoric career will be readily understood as soon as we realize the nature and extent of this success, that is to say, as soon as we realize precisely *what* it was that, for about two decades, succeeded so conspicuously, *how* it succeeded, and *why*.

Above (in Chapter 2) we have interpreted Quesnay as a philosopher of natural law. In fact, Quesnay's theories of state and society were nothing but reformulations of scholastic doctrine. The motto, *Ex natura jus, ordo, et leges* might have been, though it presumably was not, taken from St. Thomas. The physiocrat *ordre naturel* (to which there corresponds in the world of real phenomena an *ordre positif*) is the ideal dictate of human nature as revealed by human reason. What difference there is between Quesnay and the scholastics is not to the former's credit. We have seen that St. Thomas and still more the late scholastics, such as Lessius, were perfectly aware of the historical relativity of social states and institutions and that they always refused to commit themselves, in mundane affairs, to an invariable order of things. But Quesnay's ideal order is invariable. Moreover, in his paper on *Droit naturel*, he defined Physical Law as the 'regulated (*réglé*) course of all physical events which is evidently the most advantageous to mankind,' and Moral Law as 'the rule (*règle*) of every human action conforming to the physical order evidently most advantageous to mankind': these 'laws' form together what is called 'natural law,' and they are all immutable and the 'best possible ones' (*les meilleures lois possibles*). In the case of the scholastic doctors, such principles were confined to the realm of metaphysics and not directly applied to historically conditioned patterns. In the case of Quesnay they were directly applied to particular institutions, such as property. And Quesnay's political theory—*both* analytically and normatively—turned upon a monarchical absolutism in an uncritical and unhistoric manner that, as we have seen, was also quite foreign to the scholastics.[2] Now, we know how well the old natural-law system fared in the eighteenth century and how acceptable it proved to be, in its essential features, to *la raison*. Therefore, Quesnay's particular form of it, some non-essential frills excepted, fell in with the intellectual fashion of the hour: everybody readily understood this part of his teaching, sympathized with it from the start, and felt at home when discussing it. And, unlike other votaries of *la raison*, Quesnay harbored no hostility either to the Catholic Church or to the monarchy. Here, then, was *la raison*, with all its uncritical belief in progress, but without its irreligious and political fangs. Need I say that this delighted court and society?

---

[1] The term means Rule of Nature and was used by Dupont as a book title in 1767. But according to Oncken it was used earlier by Baudeau and is perhaps due to Quesnay himself. The question is of no importance.

Again, agriculture held a central position in Quesnay's program of economic policy as well as in his analytic scheme. And this feature of his teaching, too, fell in with the fashion of the hour. Just then everybody was raving about agriculture. This enthusiasm had two different sources that reinforced each other, though they were really quite independent. First, the revolution of agrarian technique gave a novel actuality to agricultural problems. It amounted to less in France than it did in England, but it produced just as much drawing-room talk in Paris as it did in London. Second, the illogical association of the natural rights of men with a glorified primitive state of society and the not less illogical association of the latter with agrarian pursuits gave to agriculture a drawing-room popularity that had, to be sure, no relation to Quesnay's serious teaching but nevertheless blew wind into his sails. We have the picture if we add one more touch. The dogmatizing doctor's apartment in the entresol of the palace of Versailles was not far from the well of all preferment, Mme de Pompadour's suite. The ambitious on the lower rungs of the ladder could hardly fail to perceive this fact, and some of them may have thought that an hour's boredom in the former was a cheap price to pay for a good word dropped in the latter. Marmontel was quite frank about this, and it is safe to assume that he was not the only one to make the discovery.

---

[2] It should be observed, however, that in Quesnay's time and country there was perhaps much practical wisdom in this. For in the actual situation of eighteenth-century France, the reforms advocated by the physiocrats could have been carried (without revolution) only by the strong hand of a despotic monarch. The hostility of the physiocrats against 'privilege' of any kind was therefore not, as one might think, in contradiction to their allegiance to monarchy but on the contrary the very reason for it.

Such things do matter at all times though different environments have different methods of favoring doctrines without absorbing, or caring for, their real scientific import, if any. Expressed in terms of that particular environment, Quesnay's success was primarily a *succès de salon*. Polite society talked physiocracy for a time but very few people outside took much notice of it except by way of sneering at it. There was thus a physiocrat fashion but there was no physiocrat movement in the sense in which there was (and is) a Marxist movement, especially not one rooted in agrarian class interests. But what about the political influence of the physiocrats of which we read so much? What about their historic role in combating privilege, abuses, and all the horrors of protection? The reader would completely misunderstand the drift of the argument presented, as well as the reasons why it was thought necessary to present it, if he concluded from what has been said so far that this influence should be equated to zero. No group so well disciplined and so bent upon propaganda as the physiocrats were can fail to exert some influence. For instance, such a group as our own League of Women Voters is a cog in our political engine that no realistic analysis of our time can afford to neglect entirely. The point is that the physiocrat group exerted this kind of influence and no other, and that their importance as a motive power of politics was small. A brief examination of Quesnay's recommendations will establish this.

These recommendations may for our purposes be reduced to two: laissez-faire, including free trade, and the single tax on the net income from land. In order to arrive at a true estimate of Quesnay's competence as a 'practical' economist, it is necessary with regard to both to distinguish doctrinal frills from underlying common sense. Thus, Quesnay taught laissez-faire and free trade as absolute norms of political wisdom. But these imperatives must be viewed in the light of the physiocrats' hostility to all kinds of privileges and to a great many things that seemed to them to be abuses, monopoly positions among others. Since these could not have been abolished without a good deal of governmental 'interference,' Quesnay urged upon government what really was an activist policy, and not at all one of doing nothing. Moreover, in spite of his wholesale condemnation of government regulation or control, it is relevant to observe that what he actually faced were regulations that were inherited from the past and no longer fitted current conditions: the absolute norm of laissez-faire acquires in such a case a relative significance that differs greatly from what its absolutism suggests. Finally, we must not forget that

French agriculture in 1760 was not interested in protection: there was no 'danger' of large wheat imports as a normal phenomenon; and free trade in agricultural products would have, if anything, increased their prices. We shall presently discover reasons for doubting whether Quesnay would have been a thorough-going free trader if he had written in 1890. Similarly, as regards his single tax, we must distinguish the common-sense idea from the trappings that made it an object of ridicule. To simplify and rationalize the French system of taxation by basing it upon a tax on net income was evidently a sensible idea. To base it *exclusively* on such a tax was a doctrinaire's way of putting this idea. To base it exclusively on a tax on the net rent of land was Quesnay's way of applying his theory that the net rent of land was the only kind of net income in existence and that any tax must ultimately fall upon it in any case. This theory may be untenable. Even if it were tenable as an abstract proposition, its application to the practical question of taxation would be indefensible because the mere presence of friction in the system would be enough to produce net returns other than the rent of land. But the value of the fundamental idea is not entirely destroyed by this particular twist. Moreover, the suggestion to tax the pure rent of land, in view of the fact that it was then not directly taxed at all, carried sense whatever the frills in which it was presented—sense that cannot be claimed for later proposals of a similar nature, such as Henry George's. The physiocrat contribution to public finance in fact stands out well in the group's textbook on it, Mirabeau's *Théorie de l'impôt* (1760). This work—Dupont called it 'sublime'—relieved the stress upon the single-tax panacea by properly emphasizing the importance of administrative reforms, of revenue from the *domaine*, the mint, the post office, a special tax on tobacco production, and a salt tax: all of this helps to remove the stigma of freakishness that has been put upon the *impôt unique*.

But observe that there was nothing in the physiocrat general program that was substantially new. The traditional assertion to the contrary may be traced (1) to the understandable desire of historians of the group to protect its priorities against A. Smith, in which they were, of course, quite right; (2) to the optical illusion that will victimize any historian of doctrine who concentrates his vision upon a particular group and pays inadequate attention to what lies around and, historically, before it; (3) to Quesnay's way of quaint and distinctive formulation, which separates his views from similar ones by overaccentuated but all the same artificial dividing lines. Thus, the single-tax idea was as we know an old one; if Quesnay can be said at all to have done something novel with it, then his contribution consists in his having given it that particular twist which few of us will hail as an improvement. In matters of free trade it may indeed be held that the physiocrats were the first *group* to advocate unconditional free trade though they had been anticipated by individuals such as Sir Dudley North. But for us this is not important. Much more important is it that as regards grasp of the scientific principles involved, many of their contemporaries, including their professed enemies such as Forbonnais, were their equals. It cannot be too often repeated that sponsorship of a particular practical conclusion proves nothing for or against a man's insight into economic causes and effects. In fact, if equality of insight be doubted at all, the doubt should be raised against Quesnay. For 'whole-hog' positions, though there are many other explanations for them, usually point to some defect in insight rather than to the contrary.

Nevertheless, Quesnay's views about the economic process and his policies being what they were, it is of course possible to trace to him practically the whole arsenal of nineteenth-century liberal argument. But all those ideas floated toward nineteenth-century writers and politicians in a much broader stream, in which the physiocrat element was but a small part. This also applies to the politicians of the *Constituante* and of the Revolution in general. Nor is there more justification for the claim that physiocrat influence was responsible either for Turgot's appointment or for his policy (see below, sec. 4). The only instances of practical influence were the experiments with the *impôt unique* made by Karl Friedrich of Baden-Durlach and by Peter Leopold, Grand Duke of Tuscany. However, it has been remarked already that Quesnay, if he got rather more than his due as a patron saint of economic liberalism, has to this day been receiving less than his due as a scientific economist, if we neglect the glowing eulogies of his immediate disciples. Especially that kind of recognition—the only serious one—that consists in the acknowledgment by competent workers of obligation, or at least of priority, in definite points, has been dealt out to him rather sparingly. One reason for this was that his analytic work was little understood and that in consequence later economists actually did not owe as much to him as one might think. Another was the presence in his teaching of what people felt to be an element of oddity. In the case of A. Smith both reasons seem to have been operative: almost certainly he did not fully grasp the importance of the *tableau économique*; quite certainly he was overanxious to avoid associating himself with anything that was in any way odd. Karl Marx was the only first-rank economist to give Quesnay his due.

[(c) *Quesnay's Economic Analysis.*] Recall Quesnay's definition of Natural Law. As soon as we realize all its implications we shall understand what those historians mean who, pointing to a theological bent in Quesnay's thought, either deny the analytic character of his work or, if they go not quite as far as that, at least hold that Quesnay's religious beliefs must have been a factor in shaping his economics.[3] There may be some truth in this as far as Quesnay's views on economic policy and his value judgments are concerned. But there is no truth in this as regards his economic theory. It is not decisive of course that Quesnay himself repeatedly claimed that he was faithfully describing facts.[4] But application of our own test yields the same result and establishes the validity of that claim: the reader will presently see that no economic proposition of Quesnay's rests upon any theological premisses or would be affected by discarding what we know about his religious beliefs. This proves ipso facto the purely analytic or 'scientific' nature of his economic work and leaves no room for extra-empirical influences. Let us now consider briefly the salient features of his theoretical set-up.

---

[3] This point will stand out particularly if we compare Quesnay's definition with Montesquieu's, whose natural laws are nothing but *rapports nécessaires qui dérivent de la nature des choses*, a definition that cannot be commended too highly.

[4] Two references may be useful: first, in the dialogue *Du commerce* (1766), where Quesnay expounds part of his theory of capital, he invites his readers to visit farms and factories in order to satisfy themselves of the realism of his theory; second, speaking of the economic relations between classes he tells us: *La marche de ce commerce*

1. All reasoning on economic topics necessarily implies recognition of an Economic Principle of some sort. Precisely because of this it is difficult to say when and by whom such a principle was first formulated. But if we wish to stress explicitness of formulation, then, I think, priority (as against the Italians) belongs to Quesnay's rule of conduct: greatest satisfaction (*jouissance*) to be attained with the smallest expense or, as he goes on to say, labor-pain. The importance of this rule or principle, considered as a contribution to formal theory—or, as we may also call it, to the pure logic of economics—consists primarily in bringing out the fact that the fundamental problem of that theory is a maximum problem. The importance of the hedonist garb in which Quesnay presented it consists in the fact that, considering dates, it gives him a prominent place in the history of utilitarian social philosophy: he certainly was one of the founding fathers of utilitarianism though he did not state the greatest-happiness principle in so many words.

But he also is the most important of all the founding fathers of the doctrine that will henceforth be referred to as the Maximum Doctrine of Perfect Competition (see A. Marshall, *Principles*, p. 531). That is to say, he held that maximum satisfaction of wants for all members of society, taken together, will result if, conditions of perfect competition prevailing, everyone be allowed to act freely upon his own individual self-interest. This doctrine was taught throughout the nineteenth century, unconditionally or with some qualification, by most nonsocialist theorists of standing, including many who refused to accept the utilitarian philosophy: serious, though at first very cautious, criticism really starts with A. Marshall. All the more necessary is it to point out how weak its foundations were from the first. The doctrine is of course never strictly true under any circumstances. But, for certain historical environments, a case can be made out for it under assumptions that are restrictive indeed, but not so restrictive as to deprive it entirely of practical value. The point to which I wish to call the reader's attention is, however, that Quesnay did not make any attempt to prove it. It did not seem to him to stand in need of explicit proof. He manifestly thought that if every individual strives to realize maximum satisfaction, then all individuals will 'of course' achieve maximum satisfaction. The fact that one of the best brains of our science could have been content with such an obvious non sequitur is indeed food for thought: low standards of rigor and sloppiness of thinking have been worse enemies of scientific economics than has been political bias.

Observe, however, that the physiocrat slogan—'the interests of individuals

---

entre les différentes classes et ses conditions essentielles ne sont point hypothétiques. Quiconque voudray réfléchir, verra qu'ils sont fidèlement copiés d'après la nature.

are the servants of the public interest'—is not per se open to our objection. It may mean no more than that, as A. Smith was to put it, we owe our bread not to the benevolence of the baker but to his self-interest, a pedestrian truth which it is worth while to repeat again and again in view of the ineradicable prejudice that every action intended to serve the profit interest must be antisocial by virtue of this fact alone. A. Smith was careful not to build too much on this. In particular, he was keenly aware of the antagonism between social classes. But Quesnay went on, from asserting universal compatibility—or, indeed, complementarity—of individual interests in competitive society, to asserting universal harmony of class interests, which makes him the forerunner of nineteenth-century Harmonism (Say, Carey, Bastiat). In this case, however, we have an attempt at proof: the *tableau économique* shows how every class, as it were, lives upon every other class, and in particular how the prosperity of the landowners conditions the prosperity of the other classes. The proof—which hails from Cantillon—is open to obvious objections and even to ridicule, but nevertheless Quesnay's harmonism does not simply hang in the air. Nor is it necessary to appeal to belief in providential ordinance in order to explain it.

II. Quesnay possessed a very comprehensive analytic schema, though he presented it by means of disconnected sketches. Some parts of it, especially those concerning population, wages, interest, and money, will come in for notice in subsequent chapters. In order not to leave the present picture incomplete, however, I shall indicate his positions on these subjects: his theory of population anticipated that of Malthus in all essentials; his theory of wages centered in a minimum-of-existence proposition; his theory of interest may be said to be almost nonexistent and he entirely failed to account for the phenomenon; his theory of money, unlike Cantillon's, was what we have decided to label cartalist.

Barter and pricing he analyzed on strictly 'subjective' lines—basing his theory resolutely upon the fact of consumers' wants. This is of some importance—though he added nothing to the price theory of the late scholastics—because his treatment of the problem (like Condillac's) must be counted among the influences that kept this theory alive in France: it points directly to J. B. Say. There is, however, another point to be recorded in this connection. A. Marshall may have been right in denying that the theory of consumption is the scientific basis of economics. But it was certainly the basis of Quesnay's economics. 'Liberal' economists of the nineteenth century were in the habit of commending eighteenth-century free traders, especially A. Smith, for having duly emphasized the truth that consumption is the 'sole end and purpose of production' and for having thereby abolished one of the 'errors of mercantilism.' There is very little to this: the truth, so far as it is a truth, is trivial and the error is largely imaginary. However, Quesnay also attended to consumption in a different sense that would have been very little to the taste of those 'liberal' economists and is, if anything, suggestive of 'mercantilist' lines of thought:[5] unlike Turgot and A. Smith, he made it an explicit condition for the economic process to function smoothly *that everybody should promptly spend his net receipts upon consumers' goods* or, to use a phrase that has gained currency in Washington in the last years, that everybody should 'utilize' his income fully. If this were not done, he thought, and especially if some people saved *in order to increase their individual stocks of money*, all classes would decay and total output would shrink, since anybody's refusal to spend necessarily destroys somebody else's income. This 'Keynesian' aspect of Quesnay's teaching will be considered later.

III. Particularly significant as a creative contribution was Quesnay's theory of capital. Cantillon and other precursors notwithstanding, he may be said to have laid the foundations of this part of economic theory. The performance is an interesting illustration of the way in which, in the mind of the born theorist, *analytic generalization may grow out of observation induced by preoccupation with practical problems*. Quesnay's agricultural program, which to him was practically equivalent to the sum total of economic policy, was geared to the needs of fairly large-scale farming: like Cantillon, he never considered seriously any agrarian world other than one that turned on, and was propelled by, the enterprise of an intelligent and active farming class in full possession of all the technological and commercial opportunities of its time. These intelligent farmers he did not visualize as owners of their land, but as free from all interference from landlords, from whom they would rent, for long periods, large lots of land—cleared and equipped with buildings—in order to do with them as they pleased. Commons should be dissolved and let to individuals like the rest of the land; feudal rights and duties—in particular the right to hunt on farm land—should be abolished; so should internal and external customs that hamper disposal of products, and taxes that discourage effort (one of the practical reasons for the single tax that was to be paid by the landlord); the countryside, as it were, was to dissolve into a swarm of prosperous enterprises, left to their own devices, selling at high prices, buzzing with energy themselves, and energizing the whole of the national economy.[6]

---

[5] Quesnay's free-trade recommendations are, of course, responsible for the tradition that put him into a position of uncompromising hostility to 'mercantilist' doctrine. We have seen, indeed, that even in those recommendations there is an element that distinguishes his free trade from the free trade of the nineteenth-century 'liberals'; viz., the emphasis upon the *bon prix*, the high price, of agricultural products. But in itself this might be interpreted as an insertion, for reasons of political preference, of a practical consideration into a doctrinal structure to which it was thoretically extraneous. Looking more closely, however, we discover that there was more than that to the *bon prix*. Unlike A. Smith, who carried the cheapness-and-plenty doctrine to victory (and therefore was, if we adopt Lord Keynes's view, a victim of the 'fallacy of cheapness'), Quesnay sponsored, *as a matter of analytic principle*, the dearness-and-plenty view (see below, ch. 6, sec. 1). And this, taken together with the point to which I am about to call attention in the text, makes him a brother in spirit, as far as analysis and not policy is concerned, of writers that are usually classed as 'mercantilists' and distances him from the nineteenth-century writers who were to follow A. Smith and from A. Smith himself, at least in one very important respect.

Now, if the reader visualizes this particular type of program, he will immediately see that its success presupposed fulfilment of three conditions: first, that these farmer-entrepreneurs should actually buzz with energy, a condition that Quesnay took lightly because, being a typical child of his age, he did not attach much importance to the problem of innate qualities of personnel; second, that this farmer's paradise should not be undersold from abroad, a condition about which, in eighteenth-century France, it was not necessary to worry; and third, that there should be plenty of capital—cheap capital—available for these essentially capitalist farmer-entrepreneurs. Quesnay did worry about this last condition. He had every reason for doing so, because his realistic studies, which went into all the details of the technology and business policy of farming, had given him a true idea of what the capital requirements of this kind of farming actually are. And it was from these investigations that, conceptualizing his findings, he developed his theory of capital. The immediate result is embodied in his classification of the farmer's capital requirements into *avances foncières*, initial expenditures on clearing, draining, fencing, building, and the like that do not recur at all or recur only in long periods, *avances primitives*, expenditures on equipment including cattle and horses and the *avances annuelles*, the current expenditures on seed, labor, and the like.[7]

Quesnay did not bother much about generalizing these concepts: their extension to include industry does not present any difficulty. But what do these *avances* consist in? It is no doubt the drainage, buildings, oxen, ploughs, seed and labor, and the like, that the farmer needs. A stock of goods and services, then? But if so, what are we to do with the facts that 'capital required' or 'capital invested' is, at the very least, *expressed* in terms of money, and that, as a matter of fact, it is also *bought* for money, which is really what landlord (for the *avances foncières*) and farmer need in the first instance? Quesnay ran up against all the problems that lurk behind these questions, and his rudimentary attempts at solving them may have been—even if they were not actually, for it is impossible to be certain about this—the starting points of all further work upon them. We shall discuss below the reasons that have been adduced for believing that A. Smith's capital theory grew out of critical absorption of Quesnay's, which would in fact make the latter the ancestor of practically all the capital theories down to J. S. Mill's. And since the man who first tackles a subject will often throw out all sorts of suggestions that point in many more directions than he himself is aware of, we might even be tempted to trace back to Quesnay such later developments as are associated with the names of Walras and Irving Fisher, on the one hand, and of Jevons and Böhm-Bawerk, on the other. This, however, is hardly permissible, for the logical possibility of doing so simply results from the rich and indefinite possibilities—of truth as well as of error—that are enshrined in the word *avances*. Of course, no writer on economic subjects can ever have doubted the simple fact that what 'capitalists' do is to provide either goods or money with which to start and carry on production; and 'capitalists' themselves always knew that what they were doing was to 'advance' money for these purposes. But one of the fundamental types of analytic achievement precisely consists in raising some simple fact (for example, that apples, severed from the branches of the apple tree, will fall to the ground) *into the light of theoretical consciousness*. This is what Quesnay's contribution to capital theory consists in: impressed by the fact that his farmer-entrepreneurs could not start upon their careers unless they were provided with all sorts of things *beforehand*, he introduced capital into economic theory as wealth accumulated previous to starting the production under consideration. But more than this he did not do, and widely divergent paths may open out from this starting point. In particular, he did not analyze the formation and behavior of money capital as a thing distinct from 'real' capital—a thing, moreover, that plays tricks of its own. And he accepted the Janus-face of nonmonetary capital, which is value on one side (*valeurs accumulées*) and physical goods on the other, without straightening out the problems involved, particularly that of the carrying charges which enter the value concept but do not enter the physical one.

---

[6] By way of supplementing what has already been said about the common sense of much of Quesnay's economic philosophy, it may be observed that a policy of this kind seems indeed a more reasonable thing to recommend, in the domestic and international situation of France around 1750 or 1760, than throwing away means on colonial ventures which, even if successful, would only provide prizes for the English fleet, or on financial enterprise that might end as John Law's had ended, or on military establishments that might produce another Rossbach. This psychology of the thoroughly disappointed nation that Quesnay was addressing must be understood.

[7] There are in addition the *avances souveraines*, public expenditure on roads, et cetera.

IV. The third chapter of Book II of Marshall's *Principles* opens with the sentence, 'Man cannot create material things.' This statement hails from J. S. Mill and Rae and many earlier writers. Since economics is concerned with the 'creation' or production of either utilities or market values, it is difficult to see the relevance of such a statement, of which, in fact, none of those writers ever made any use. But, as everyone knows, the physiocrats did put it to analytic use: following Cantillon they derived from it their theory of the *produit net*. This is the only reason why the subject crosses our path again. For neither their statement of what they believed to be a physical fact nor the philosophies in which they indulged in connection with it are in themselves worth our while to discuss. Nor would there be anything particularly interesting in Quesnay's terminological decision to call, on the strength of that fact, agricultural activity 'productive' (the farmer's activity, not that of the farm laborer) and every other activity 'sterile' (which, of course, does not mean useless), though it is precisely this which was felt to be odd and attracted an undue amount of critical attention. Let us, however, observe that it is really not so very odd to look upon an economy as an engine that is fed materials drawn from the womb of nature and that simply works up these materials without adding to them: the only question that arises is whether or not the analogy is useful. After what has been said on the subject in our survey of Cantillon's work, we can dispose of it quickly.

We have seen in that survey that the theory of Cantillon's *produit de la terre*—and Quesnay's *produit net* is the same thing—is a method, though certainly not the most correct or convenient one, of expressing the fact that the rent of land is, or contains, a net return. But, as we have also seen, the theory goes further than this. It holds that the rent of land is the only net return in existence, and that it is coextensive with the whole of society's disposable net income, all other returns being balanced by cost items in the sense that they are not more than sufficient to replace what production uses up. The workman gets no more than is necessary to reproduce his ability to work. The capitalist, taking account of risks, gets no more than is necessary to replace his stock and *his* ability to work: labor, management, and capital are 'sterile' in the sense that, though they produce utilities, they do not produce any Surplus Value.

In general conception this theory bears a striking similarity to that of Marx. Exactly as Quesnay let land alone be productive of surplus value, so Marx let labor alone be productive of surplus value. Neither construction allows any productivity to capital—meaning plant, equipment, and material—which is indeed a conductor or embodiment of a surplus value created, respectively, by land or labor but does not add to it. So far Marx's theory looks as if it were the result of switching Quesnay's schema from one of Petty's two original factors of production to the other. There seems, however, to be a fundamental difference between the two. Marx's way of carrying out his postulate of productivity's being inherent in labor alone is, as we shall see, open to objection. But, with him, labor's productivity is from the first a value productivity, and he attempted to show, on the basis of his law of values, how surplus value emerges from the mechanism of competitive markets. Quesnay made no such attempt. His starting point was physical productivity, that is, 'creation' of stuff and not of values. He took it for granted that the fact of physical productivity implied value productivity, and he shifted in midstream from the one to the other. On the face of it, this seems to be a definite error of which Marx was not guilty. But we have seen above that, by means of suitable assumptions, it is nevertheless possible to make the proposition that the rent of land is the only net return formally valid. And this means in turn that if we grant these assumptions—which are, after all, not much worse than those which it is necessary to grant in order to validate the labor theory of value—it is possible to transpose Quesnay's irrelevant argument from physical productivity into a relevant one from value productivity: the scarce natural agent, by hypothesis operating in agriculture alone, produces a value surplus over the other factors there employed, and manufacture adds nothing to it because competition will reduce what it does add to the value of the materials to the level of the value of the agrarian products that the manufacturers and their workmen consume. If we be grimly resolved to go through with this argument, even interest could be explained as a derivate of the *produit net*. This would complete the analogy with Marx.

(d) *The Tableau Économique.* The analytic structure we have been surveying is logically quite complete, and he who knows how to piece it together—which Quesnay did not do—will not miss any of the essentials that go into a comprehensive treatise on pure and applied economics. The over-all description of a stationary economic process which Quesnay embodied in his *tableau* is not, as his pupils and practically all critics believed, the centerpiece of that structure but an addition to it that is separable from the rest—painted, as it were, on a separate canvas—and therefore can be dealt with separately. What it depicts is the flow of expenditures and products between social classes, which here become the actors in the economic play—which they are not in the rest of Quesnay's work.

Economists, of course, always had some schema of the class structure of society at the back of their minds. Cantillon seems, however, to have been the first to construct such a schema explicitly and to use it as a tool of analysis. This schema was adopted by Quesnay. Accordingly, he distinguished landowners (*classe des propriétaires*, or *classe souveraine* or, what is significant, *classe distributive*), farmers (*classe productive*), and all the people engaged in nonagricultural pursuits, roughly equivalent to the bourgeoisie (*classe stérile*). Labor may either be treated as a fourth class or added in proper proportions to the second and third. The latter seems preferable in order to bring out the nature of the schema, which is not so much a schema of classes as sociological entities, but of economic groups of the kind we meet in the familiar statistics of people 'attached' to, say, agriculture or mining or manufacturing industries. In any case, however, labor plays an entirely 'passive' role with him exactly as it did with Cantillon. The flow of expenditures and products, then, is between a 'farmer basin,' a 'landowner basin,' and a 'sterile-class basin.' It is not necessary to reproduce Quesnay's picture of it or to enter into its details.[8] All the reader needs to retain is this.

Suppose that in the unit period t-1 the landowners have received and accumulated in many instalments the rent due them by the farmers, so that, at the beginning of period *t*, they hold in cash all the net national income (in Quesnay's sense) while everybody else stands ready to sell and to produce. We are to follow the meanderings of that rent or net income through the economy. Let its amount be 1000 units of money. The landowners, so we will further assume, spend 500 of this on farm products and 500 on manufactures, the products of the sterile class, that is, the class that does not produce surplus value. The 500 units that the farmers get back in this way (for these units came out of their payments in *t*-1) are first of all doubled in their hands in consequence of their surplus value-producing activity so that they swell up to 1000. Half of this then goes to the landlords for rent (not to be spent until period *t* + 1), one quarter is 'consumed' within the agrarian sector, the last quarter goes to the 'steriles' in payment of manufactures for the farmers' use. The 'steriles' do not add any value but only reproduce it. Of the 500 they received from the landlords, 250 units are absorbed by their and their workmen's consumption of their own products. For the other 250 they buy food and raw material from farmers in whose hands these 250 again swell up to 500. And the same happens with the 250 and any later amounts they get from farmers. Whatever the farmers receive is always doubled and used for payment of rent to the landlords to be spent in period *t* + 1 for consumption in the agrarian sector and for further purchases from the 'steriles.' It will be readily seen that, if the length of the unit period be properly chosen, we shall find at the end of it that the 1000 units of net income are back again in the hands of the landowners, who will, at the beginning of period *t* + 1, spend them and so start the whole process again. The reader will realize that all this, apart from the pictorial form, amounts to no more than a development in fuller detail of Cantillon's schema.[9] But what is the use of this picture, and what is the nature of the analytic achievement it embodies?

---

[8] As already stated, the *Tableau économique* ('picture' would render the meaning better than does the more usual 'table') was first printed in Versailles, 1758, with much pomp and circumstance—Louis XV himself, so we are told, correcting the proofs. This original, lost for over a hundred years, was recovered and reproduced in facsimile for the British Economic Society (as the Royal Economic Society then was called) in 1895 with a valuable introduction by H. Higgs, and has been repeatedly reprinted since. But Quesnay himself published another simplified version in the *Analyse* (see *Oeuvres*), which Dupont used in his *Physiocratie*. The reader finds a translation of Quesnay's commentary in A. E. Monroe's *Early Economic Thought*. Mirabeau, in the sixth Part of *L'Ami* presented a version of his own. There are thus at least two *tableaux* (disregarding variants that differ but little), which not only use different figures but also differ somewhat in theoretically relevant features. We shall not, however, go into these matters. The best way to get the essential idea with a minimum of trouble is to look up the excellent presentation by Shigeto Tsuru in Appendix A to P. M. Sweezy's *Theory of Capitalist Development* (1942).

It should be observed at the outset that so far as the idea of such a schema is concerned the specifically physiocrat features in the Cantillon-Quesnay

---

[9] The question how 'credit' should be distributed between Cantillon and Quesnay is both difficult and, from the standpoint of the sociology of scientific invention and scientific success, interesting. Cantillon no doubt felt the scientific need for some such tool, had the idea of how to construct one, *and* actually pointed the way toward doing so. If one of these three criteria for attributing inventions to individuals had been absent, the case would be much easier to deal with: as it is, Cantillon did for the *tableau* method what *both* Newcomen and Watt did for the steam engine. Yet I frankly confess to a reluctance toward attributing to Quesnay no more than the merit of sharpening Cantillon's concepts and putting results into the *tableau* form which puzzled and attracted. Such deep understanding and wholehearted absorption of another man's work is rare unless it is propelled by original perception of the same thing. Moreover, as will presently be pointed out in the text, an essential part of the achievement was the circuit flow idea. It is tempting to assume that this idea came independently to Quesnay, the physician, through analogy with the circulation of the blood in the human body. William Harvey's (1578-1657) discovery of the latter was then a century old but had lost nothing of its freshness (*Exercitatio anatomica de motu cordis et sanguinis*, 1628).

tableau are irrelevant. Having dealt with these already, we are therefore no longer interested in the central position Cantillon and Quesnay assigned to landowners and their expenditure: we could just as well start from one of the two other 'basins.' Nor are we any longer interested in what was of primary importance to Quesnay, namely the principle that every sum that goes to farmers increases (doubles) in their hands and that sums that go to manufacturers do not. Every analyst can arrange these points so as to suit his theoretical set-up. What we are now interested in is the *tableau* idea considered as a tool, the *tableau* method itself. Three aspects of it call particularly for attention.

First of all, the *tableau* method achieves a tremendous simplification. Actually the economic life of a nonsocialist society consists of millions of relations or flows between individual firms and households. We can establish certain theorems about them, but we can never observe all of them. But if we replace them by relations between classes or by flows of class (or other) aggregates, the unmanageable number of variables in the economic problem suddenly reduces to a few which are easy to handle and follow up. Reserving this aspect for later discussion, we take the opportunity of noticing a cognate though different point. A glance at the *tableau* suggests the idea of a Social Product or Total Output that is produced in one series of steps and 'distributed' in another. We are so familiar with this idea that we rarely if ever realize how very unrealistic an abstraction it is. Production and distribution are indeed different processes in a socialist society. But in capitalist society they are but different aspects of one and the same process: the bulk of capitalist incomes is formed in the course of the transactions that constitute production in the economic, as distinguished from the technological, sense. Nevertheless, the realistic idea of income formation—the realistic virtue of which moreover does not carry any disadvantage that might justify its neglect—has come to the fore only sporadically.[10] With the French economists, the physiocrat idea of distribution prevailed throughout and the same holds true of English economists who adopted it, perhaps, under the influence of J. B. Say, at the beginning of the nineteenth century. The concept of total annual output and its value (*valeur de la reproduction annuelle*) has, of course, its uses independently of this. It was adopted by A. Smith.

Second, the simplification of the analytic pattern achieved by the *tableau* method opens up great possibilities for numerical theory. Quesnay was more alive to these possibilities than had been Cantillon and, in this particular respect, he carried the latter's work much further. He troubled himself about statistical data and actually tried to estimate the values of annual output and other aggregates. That is to say, he did genuinely econometric work. This aspect, too, has acquired new actuality in our time through the great work of Leontief,[11] which, entirely different though it is from Quesnay's in purpose and technique, nevertheless revived the fundamental principle of the *tableau* method. Marx, who stands between the two, did not attempt to make his schema statistically operative.[12]

---

[10] The first to urge the case for income formation vs. distribution was, I believe, E. von Philippovich (in the later editions of his textbook, *Grundriss der politischen Oekonomie*, 1st ed., 1893-1907).

[11] Wassily W. Leontief, *The Structure of the American Economy* (1941; new rev. ed., 1951).

Third and most important, the Cantillon-Quesnay *tableau* was the first method ever devised in order to convey an *explicit* conception of the nature of economic equilibrium. It would seem impossible to exaggerate the importance of this achievement if admiring disciples had not actually succeeded in doing so. Economics, like every other science, started with the investigation of 'local' relations between two or more economic quantities, such as the relation between the price of a commodity and the quantity of it that is available in a market; in other words, it starts with Partial Analysis (see below, Part IV, ch. 7, sec. 6). Disconnected efforts of this type were directed toward points that happen to be of some practical interest or to attract our curiosity for other reasons. It was but slowly that the fact began to dawn upon analysts that there is a pervading interdependence between all economic phenomena, that they all hang together somehow. We have seen that the best of the seventeenth-century Discourses of Trade, such as Child's or Pollexfen's or, still more, the writings of Davenant, display unmistakable symptoms of a growing awareness of this. But they never bothered to investigate *how* things hang together. They took it for granted and either were unable to raise this interdependence to the plane of explicit formulation or did not see the necessity for doing so. They were very far from realizing that this all-pervading interdependence is the fundamental fact, the analysis of which is the chief source of the additions that the specifically scientific attitude has to make to the practical man's knowledge of economic phenomena; and that the most fundamental of all specifically scientific questions is the question whether analysis of that interdependence will yield relations sufficient to determine—if possible, uniquely—all the prices and quantities of products and productive services that constitute the economic 'system.' I have said on a previous occasion that the first discovery of a science is the discovery of itself. But this does not spell discovery of its fundamental problem. That comes much later. In the case of economics, it came particularly late. The scholastics had an inkling of it. The seventeenth-century businessmen-economists came nearer to it. Isnard, A. Smith, J. B. Say, Ricardo, and others all struggled or rather fumbled for it, every one of them in his own way. But the discovery was not fully made until Walras, whose system of equations, defining (static) equilibrium in a system of interdependent quantities, is the Magna Carta of economic theory—the technical imperfections of that monument of constitutional law being an essential part of the analogy (see below, Part IV, ch. 7, sec. 7). The history of economic analysis or, at any rate, of its 'pure' kernel, from Child to Walras might be written in terms of this conception's gradual emergence into the light of consciousness.

Now Cantillon and Quesnay had this conception of the general interdependence of all sectors and all elements of the economic process in which—so Dupont actually put it—nothing stands alone and all things hang together.

---

[12] On Marx's reproduction schema see P. M. Sweezy, op. cit. Appendix A.

And their distinctive merit—shared, to some extent, by Boisguillebert—was that, without realizing the possibilities of the method later on adumbrated by Isnard, they made that conception explicit in a way of their own, namely, by the *tableau* method: while the idea of representing the pure logic of the economic process by a system of simultaneous equations was quite outside their range of vision, they represented it by a picture. In a sense, this method was primitive and lacking in rigor—which is, in fact, why it fell out of the running and why analysis historically developed on the other line. But in one respect it was superior to the logically more satisfactory method; it visualized the (stationary) economic process as a circuit flow that in each period returns upon itself. This is not only a method of conveying the fact that the economic process is logically self-contained, a distinct thing that is complete in itself, but it is also a method of conveying features of it—definite sequences in particular—that do not stand out equally well in a system of simultaneous equations. Of course, there is also the simplification of the theory of general equilibrium adverted to already: Quesnay identified general equilibrium, that is, equilibrium in the economy as a whole in distinction to the equilibrium in any particular small sector of it, with the equilibrium of social aggregates—exactly as do the modern Keynesians.[13]

4. TURGOT

Although Turgot was no econometrician, his great name has been assigned this place in our gallery because he is so often classed with the physiocrats, though mostly with qualifications. At first sight, this seems reasonable enough, for his main work abounds in passages that are evidently intended to emphasize allegiance to specifically physiocrat tenets. We read that land is the *only* source of *richesses*; that the *cultivateur* produces not only his own compensation but also the income that serves to remunerate the class of artisans and other *stipendiés*; that the farmer's activity is the prime mover of the social engine, whereas the manufacturer's only transforms; that the farmer supports and feeds all other classes; and so on. But, if we look more closely, we make a surprising discovery. Those passages are then seen to be strangers to the argument into which they are inserted. We can suppress them without affecting the rest. In fact, the rest gains in consistency thereby. Therefore, if we adhere to a principle that is uniformly applied in this book to the interpretation of such professions of faith, namely, the principle of relevance to analytic procedure and results, we have no choice but to neglect those passages. What are we to think of this? First of all, commonly accepted rules of criticism would lead us to suspect those passages if we were dealing with an ancient text. And it so happens that in this particular case such distrust is not completely unwarranted. For we know that there was a not quite amicable discussion between Dupont and Turgot on the subject of the publication of the latter's manuscript, and we do not know exactly what the result was. However, I will waive this point. But quite independently of it, there is, considering what we know of Turgot's generous character, no difficulty in understanding why, writing for publication at that particular time, he should have gone out of his way to pay respect to a group with which he agreed on many points of scientific economics—from which he had, perhaps, learned a good deal, for example, in matters of capital theory—and with which he agreed wholeheartedly on all the immediately practical points of economic policy, though he disagreed with them on some points of their political philosophy. According to this hypothesis, which puts him, morally, high above all those who emphasize points of difference in order to distance themselves from fellow workers to whom they owe obligation, he should not be classified as a physiocrat with reservations, but as a nonphysiocrat with physiocrat sympathies. This seems, in fact, to meet the case.

---

[13] See in particular Joan Robinson, 'The Theory of Money and the Analysis of Output,' *Review of Economic Studies*, October 1933.

We went to the trouble of disentangling Turgot from the physiocrats not only in order to make his figure stand upon its own pedestal, as it should, but also in order to put this pedestal into the right place. For more closely than with the physiocrats was he associated with another group, if 'group' is the word for a very loose connection that was no school in the proper sense of the term. It centered in a strong and influential man, who was no doctrinaire, however, and no exponent of any 'system'—Gournay.[1] This fact throws much light on Turgot's background as an economist. Gournay had traveled extensively and was an intelligent observer of English developments. Much of what we know about his views has a distinctly English flavor. And among his writings are several translations, in particular one of Child's *New Discourse*. Turgot was his personal friend and was also interested in the works of English economists, especially Hume and Josiah Tucker, whom he translated. If the obvious inference may be trusted, we have here an instance of the way in which not only political but also scientific ideas crossed and recrossed the Channel. The possible filiation Child-Hume-Turgot is particularly interesting—still more so in case we have to add the name of A. Smith after that of Turgot.[2] In the French part of his background, the most important figure is Cantillon.

---

[1] Jacques C. M. Vincent de Gournay (1712-59) was a bourgeois businessman (the 'de Gournay' came from an estate that was left to him by a business connection) who later in life made himself a public servant by the purchase of the office of intendant of commerce. He was an altogether superior sort of person of a type that is rare outside England. But his great services to economics are by no means easy to characterize. They are not embodied in publications (he wrote reports, though, and also notes to translations of English economic works). Nor are his letters and various utterances (one of which has become famous: *laissez faire, laissez passer* has been attributed to him) adequate to convey what he means to the history of our science. We know pretty well his role in shaping opinion on economic policy by exerting formative influence upon some of the best minds of the age, and we also know in a general way what it was he advocated: relaxation of the fetters of public control, moderate protection, and that sort of thing. But we can only *sense*, or reconstruct from a few indications, the formative influence upon analytic work. He appointed himself, as it were, tutor to his friends, whom he knew how to choose and, like a good tutor, he effaced himself in order to give stimulating pointers to other people's teaching. His two provable claims to our gratitude are his successful propaganda for Cantillon's work and his contribution to Turgot's education as an economist. But below these two peak achievements there must have been broader middle ranges. In the highest sense of the word Teacher, this man who never taught in the technical sense may have been one of the greatest teachers of economics that ever lived. Therefore it seems that the traditional place that practically every textbook on the history of economics or economic thought accords to him is well merited, however slender the direct evidence that justifies it. The whole literature on physiocracy deals with him. G. Schelle's *Vincent de Gournay* (1897) is still the standard work. See also Turgot's '*Éloge de Vincent de Gournay*' in the latter's *Oeuvres,* and A. Oncken's *Die Maxime: Laissez faire et laissez passer . . .* (1886).

Turgot's brilliant achievements, his unchallenged place in the history of our science, and his evident title to membership in the triumvirate in which Beccaria and A. Smith are his colleagues are sufficient reasons why it is desirable to look for a moment at the man and his career. Anne Robert Jacques Turgot, Baron de l'Aulne (1727-81; referred to, by his contemporaries, as M. de Turgot; before 1750, he was known as Abbé de Brucourt), came from a Norman family that was of old, if not high, nobility and fairly well to do, if not rich. The sociological type is rendered by the English word 'gentry' and by the German word 'Junker.' He was, as a third son, educated for the Church, and this clerical education, which gave full scope to his brilliant and precocious gifts, ought to receive recognition, though it usually does not, in an enumeration of the factors that made for his achievements. He emerged full of great plans and master of wide horizons (scientifically and otherwise) as an abbé at the Sorbonne, where he became quite a figure, writing, discussing, experiencing the second formative influence of his youth, that of the 'secte encyclopédiste,' though he very soon moved away from it. Then he exchanged the career of churchman for the civil service, and a civil servant he remained for the rest of his active life. The bureaucracies of all times and countries may be proud of him, for not only was he an ornament of the French bureaucracy of the *ancien régime*, but this bureaucracy also was the third of the environmental influences that helped to form him. He was a great success as *intendant* (general administrator) of the district (généralité) of Limoges, 1761-74, where his zeal, resourcefulness, and public spirit showed up to best advantage. On the strength of this success he was appointed, in 1774, Minister of the Navy and, a few months later, *Contrôleur Général des Finances* (which means Minister of Finance and Commerce and Commissioner of Public Works), a position he held for twenty months, much of the time tortured by gout. After his fall, he lived in retirement until his death.

Except for the just pride we economists may take in so brilliant a fellow worker, the main importance of this career for a history of economic analysis is that it explains why Turgot's scientific work did not come to full fruition. Biographers and historians of economic thought, however, have always allocated most of their space to his exploits as a minister of finance and, in dealing with them, have propagated two sagas that have a bearing upon the sociology of our science and must therefore be briefly noticed. Before doing so I wish, however, to disclaim any intention of 'debunking' the fame of one of the none too numerous significant figures of which the history of economics can boast: it goes without saying that nobody would think of writing a volume on Great Ministers of Finance without including Turgot. The first of those sagas might be entitled: 'The Economist in Action.' It depicts the man who, from scientific analysis, derives recipes for curing the ills of the state and, on attaining power, rushes to carry them into effect. There is nothing whatever in this. Turgot was, first and last, a great civil servant, who looked upon state and society with the eyes of a civil servant. So, when he attained cabinet office—'power' would be a misleading term to use—he set about to improve the financial administration and the all but desperate situation of the royal finances. In both these respects he succeeded remarkably—in fact almost unbelievably—well, and these were his main achievements. He also established, by royal decree, internal free trade in grains and—the only other measure relevant for us—abolished the *jurandes*, the craft guilds. These and some minor measures were not successes in the political sense mainly because of his failure to consider tactical aspects: they immediately elicited violent resistance, the one concerning the grain trade through a piece of bad luck—its coincidence with a bad harvest. The point to be observed is, however, that nothing Turgot actually did or showed any intention of doing has any particular relation to any doctrine, scientific or other. It was all in the line of an unusually able civil servant who perceived the currents of his time and tried to serve them in a practical spirit. He was so little given to obeying abstract principles—which of course is all to his credit—that, in one instance, he actually introduced a protective duty, and, in another, embarked upon state enterprise (in the chemical industry). The physiocrats applauded him, of course, and made propaganda for him, but they had little to do with his policies and nothing to do with his advent to office, for in 1774 they were in no position to exert any influence. By the same token, his fall was not a defeat of any doctrine that was specifically their own.

---

[2] See below, ch. 6, sec. 6.

The other saga derives from the saga of the French Revolution. Since most of the writers on Turgot were and are in sympathy with the latter, they were and are inevitably driven to exalting into 'heroes that fought for the light in the darkness of despotism' a chosen few of the servants of the *ancien régime*. Turgot is the chief beneficiary of this tradition that was initiated by the revolutionaries themselves, who, even officially, sometimes referred to Turgot as *ce bon citoyen*. And some writers have added the touch that Turgot was raised to office by the voice of the people and dismissed at the behest of an intriguing court. As a matter of fact, Turgot was appointed *Contrôleur* by a thoroughly well-meaning monarch who looked around among his bureaucrats for the best man for the job. If there was any other influence, it was that of the Minister de Maurepas. As soon as he was in office Turgot, no doubt with the most meritorious intentions, began to lean heavily on the royal prerogative. Now it is very easy, when a minister is supported by a monarch, to draw up excellent decrees and to force them down the throats of *parlements* who refuse to register them. The difficulty, since government is carried on among living people and groups, is to make those decrees accepted. Louis XVI at first lent his wholehearted support, but the trouble with him, who had many good qualities, was precisely that he was no despot and quite unwilling to use force. And though Turgot was also the target of court and other intrigues—of the former, mainly owing to his policy of retrenchment—it was the popular resistance of the rural proletariat and of craft guilds that became after a time the dominant factor of the situation: there were even local revolts which Turgot suppressed with a firm hand. It would not be true either, but it would be nearer the truth than is the opposite, to say that Turgot was raised to ministerial office by the king and overthrown by the people. For our purpose, the relevance of this is in the light it sheds on the personality of one of the greatest scientific economists of all times. The interpretation submitted makes the king come off better than does the usual one but, what alone matters here, it does not make Turgot come off worse. It only makes him come off differently. We see the excellent civil servant who is a good administrator and (perhaps) adviser but no leader or tactician. We also see honesty and firmness (quite as much as do other interpreters) and (what does not, perhaps, impress these other interpreters quite as much) loyalty to his king. The answer to the academic question that has been raised, whether or not, had he stayed in office, he might have prevented the Revolution, depends on what we mean by revolution. If we mean the overthrow of the monarchy and the sanguinary excesses, the answer should be in the affirmative: no more, however, because of the reforms he might have carried in that case than because of his willingness to call out the troops. No cap of liberty will fit Turgot.

His chief work, the *Réflexions sur la formation et la distribution des richesses*, was written for the benefit of two Chinese students in 1766, and published (as has been stated above, not without some friction that arose from Dupont's attempts at editorial interference, presumably made in the interest of physiocrat orthodoxy) in the *Éphémérides* (1769-70; English trans. 1898). Of minor publications that usefully supplement this work, the most important are the *Éloge de Gournay*, the letter on paper money to the Abbé de Cicé (his first economic publication, 1749), the *observations* on the essays by St. Péravy (1767) and Graslin (1767) on indirect taxation, and a paper on loans of money (1769). His contributions to the *Encyclopédie*, including such topics as 'existence,' 'expansibility,' and 'etymology,' and his criticism of Berkeley's philosophy—and many others—are interesting as so many proofs of the breadth of his range. The *Oeuvres* of Turgot were edited by Dupont de Nemours (1808-11) and again by G. Schelle (1913-23), the latter edition being the one to use. Léon Say's *Turgot* has been translated into English by M. B. Anderson (1888). Also see Alfred Neymarck, *Turgot* . . . (1885); S. Feilbogen, *Smith und Turgot* (1892); W. W. Stephens, *The Life and Writings of Turgot* (1895); and especially G. Schelle, *Turgot* (1909).

If we now try to compare Turgot's scientific personality with those of Beccaria and A. Smith, significant similarities strike us first: all three were polyhistoric in learning and range of vision; all three stood outside the arena of business and political pursuits; all three displayed single-minded devotion to the duty in hand. Turgot was undoubtedly the most brilliant of the three, though his brilliance was somewhat tinged with superficiality, not in economics, but in his outlying intellectual domains. The main difference, from the standpoint of their scientific achievement, is that A. Smith expended very little of his energies on nonscientific work, Beccaria very much, and Turgot, from 1761 on, almost all he had. During the thirteen years at Limoges, Turgot can have had but scanty leisure; during his (nearly) two years of ministerial office, practically none: his creative work must have been done between the ages of 18 and 34. And this explains all there is to explain, not indeed about the comparative merits of the three works in question, but about the different degrees to which they were finished works at all.

Turgot was much too able a man to write anything insignificant. Nevertheless, only the Turgot specialist needs to go beyond the *Réflexions*, and with one exception we shall confine ourselves to this. The slender work was evidently written in hot haste and never thoroughly revised. It looks as Marshall's *Principles* would look if text, notes, and appendices were destroyed and only the marginal summaries—and not all of those—were preserved. In fact, it is not much more than a very elaborate analytic table of contents written for a bulky but nonexistent treatise. Such as it is, however, Turgot's theoretical skeleton is, even irrespective of its priority, distinctly superior to the theoretical skeleton of the *Wealth of Nations*. In order to arrive at this opinion, it is not necessary to impute to Turgot anything he did not actually say or to credit him with any implications of what he did say that he may possibly not have seen himself. He actually delivered the goods. In calling the work unfinished or a skeleton, I do not mean to say that there is need for uncertain conjecture or generosity of interpretation in order to finish it. It presents a complete system of economic theory. What is lacking any competent economist could supply without adding (except criticism) from his own stock of knowledge. Of course, nobody admires the *Wealth of Nations* for its theoretical skeleton alone. It owes its position to its mature wisdom, its luxuriant illustrations, its effective advocacy of policies. And there is, also, something to be said for the ponderous creation of the academic professional: it was the product of patience, of meticulous care, of self-discipline—and we cannot be sure that Turgot would ever have produced something comparable to it, even if he had had all the leisure in the world. Still, a lesson does follow from the very different success of both works: in economics, at least, intellectual performance is not enough; finish counts; and so do elaboration, application, and illustration; even now the days are far off when it will be possible, as it is in physics, to shape international thought by an article that covers less than one page. Turgot's contribution fared as well as it did because of his eminence in another walk of life. Even so it never bore the fruits that it easily might have borne.

Since the only satisfactory way of summarizing that summary is to transcribe it, and since, moreover, the most important points will be touched upon in subsequent chapters, only a few general comments will be offered here instead of a Reader's Guide. Roughly the first third of the treatise—the first 31 sections[3]—presents the groundwork including the Cantillon-Quesnay schema of classes and an analysis of their relations in production and distribution that is splashed with physiocrat colors. Certain fundamental propositions, like the proposition that competition always reduces wages to the minimum-of-existence level, are insisted on from the first. Sections XXXII-L contain a theory of barter, price, and money that, so far as it goes, is almost faultless, and, barring explicit formulation of the marginal principle, within measurable distance of that of Böhm-Bawerk. The rest of the treatise is devoted mainly to a capital theory that anticipates most of the nineteenth-century work, and to the subjects of interest, saving and investment, and capital values. Originality in individual points is difficult to assert or to deny, the more so because Turgot does not quote—which is no reproach in the case of such a sketch. But comprehensive vision of all the essential facts and their interrelations plus excellence of formulation are in evidence to a degree that would make the whole of the work an original contribution even if no individual point had been exclusively Turgot's own. And there are practically no definite errors to be found in this first of all the treatises on Value and Distribution that were to become so popular in the later decades of the nineteenth century. It is not too much to say that analytic economics took a century to get where it could have got in twenty years after the publication of Turgot's treatise had its content been properly understood and absorbed by an alert profession. As it was, even J. B. Say—the most important link between Turgot and Walras—did not know how to exploit it fully.

---

[3] [Apparently, the numbering of the sections in the Schelle edition of the *Oeuvres* differs slightly from the original version in the *Éphémérides* where one (or more) of the sections was suppressed. See ch. 6, sec. 7, n. 5.]

CHAPTER 5

Population, Returns, Wages, and Employment

1. THE PRINCIPLE OF POPULATION 250
  [(a) *The Populationist Attitude*] 251
  [(b) *Growth of Factual Knowledge*] 253
  [(c) *Emergence of the 'Malthusian' Principle*] 254
2. INCREASING AND DECREASING RETURNS AND THE THEORY OF RENT 258
  [(a) *Increasing Returns*] 258
  [(b) *Decreasing Returns: Steuart and Turgot*] 259
  [(c) *Historical Increasing Returns*] 262
  [(d) *Rent of Land*] 263
3. WAGES 266
4. UNEMPLOYMENT AND THE 'STATE OF THE POOR' 270

1. THE PRINCIPLE OF POPULATION

THE PROBLEMS of population, that is to say, the questions what it is that determines the size of human societies and what the consequences are that attend the increase or decrease in the number of a country's inhabitants, might well be the first to occur to a perfectly detached observer as soon as he looks at those societies in a spirit of scientific curiosity. The view that the key to historical processes is to be found in the variation of populations, though one-sided, is at least as reasonable as is any other theory of history that proceeds from the prejudice that there must be a single prime mover of social or economic evolution—such as technology, religion, race, class struggle, capital formation, and what not. Thus it is quite understandable that population problems should have received attention in the very beginnings of economic analysis; that they should have loomed large in the thought of all leading writers of the period under discussion; and that they should have been given a place of honor in the one great pre-Smithian system of economics that England produced, Sir James Steuart's *Principles*.

But there was also a practical reason for this prominence of population problems. Ever since primitive tribes had solved theirs by abortion and infanticide, people in general and social philosophers in particular never ceased to worry about them. Roughly speaking until the end of the sixteenth century, the trouble arose from a relation between birth rates and death rates that was incompatible with stationary or quasi-stationary economic environments: the problem of population was one of actual or threatening overpopulation. It was from this angle that it presented itself to Plato and Aristotle. The opposite type of trouble was quite exceptional—the outstanding example is the decay of the native Roman stock in the last century of the Republic and throughout the epoch of the Empire. In the Middle Ages the dwelling places of the lower stratum of the warrior class, the simple knights, suffered from overcrowding whenever there were no crusades, wars of the Roses, epidemics, and so on to reduce numbers; and the artisans' guilds offered livelihood for restricted numbers only and experienced perennial difficulties with ever-lengthening 'waiting lists.' But all this changed during the seventeenth and eighteenth centuries. We have seen that the practical economic problems of those centuries were the problems of countries that were poor in goods but rich in possibilities. Seen against these possibilities, the population problem became one of underpopulation. Moreover, some countries, particularly Germany and Spain, had actually experienced depopulation for decades together.[1] And, as we have also seen, these conditions prevailed when ideas of national or territorial power and expansion filled everybody's thought and heart.

[(a) *The Populationist Attitude.*] Accordingly, governments began to favor increase in population by all means at their command. Measures differed from time to time and from country to country but were in some cases—for instance in France under Colbert—as energetic as any that have been resorted to by modern dictators. Economists fell in with the humors of their age. With rare exceptions they were enthusiastic about 'populousness' and rapid increase in numbers. In fact, until the middle of the eighteenth century, they were as nearly unanimous in this 'populationist' attitude as they have ever been in anything. A numerous and increasing population was the most important *symptom* of wealth; it was the chief *cause* of wealth; it *was* wealth itself—the greatest asset for any nation to have. Utterances of this kind were so numerous as to render quotation superfluous. In England, in particular, the first-flight men who go on record as leaders of populationist sentiment, such as Child, Petty, Barbon, Davenant, were joined by almost all the rank and file.[2] That German and Spanish writers went further than any others is amply explained by the conditions of their countries. Since Italy had a comparatively dense population and was least favored as regards opportunities for national expansion, the Italian economists went less far in this direction and, later on, less far in the opposite one than did their English and French brethren. As always, the one question that interests us is: what was the economic rationale of all this, if indeed economic analysis had anything to do with it at all? The answer should be obvious. The analytic complement of the populationist attitude boils down to one proposition: *under prevailing conditions*, increase in heads would increase real income per head. And this proposition was manifestly correct.

---

[1] German and especially Spanish writers may have exaggerated the extent to which there was depopulation. The fact itself is nevertheless beyond doubt.

[2] Most of those writers came within the traditional category of 'mercantilists,' who as a group have been charged with the famous 'confusion' between wealth and money or gold and silver which will have to be noticed later on. It is interesting to note, therefore, that some of the writers who seem to be most guilty of that confusion, such as the author of *Britannia Languens* (W. Petyt), at the same time 'confuse' wealth with size of population. That author, for instance, expressly stated that 'people are . . . the chiefest, most fundamental, and precious commodity.' Should not this make us pause before we take either of these 'confusions' too literally? But there were also dissenting voices. One of the earliest of them was that of Malynes, who already pointed to the 'positive checks' that increase would eventually bring into operation.

With unimportant exceptions, these conditions did not substantially change in the eighteenth century or even in the first decades of the nineteenth. Therefore, it is quite a problem to explain why the opposite attitude—which might be called anti-populationist or, to associate it with the name of the man who made it a popular success in the nineteenth century, Malthusian—should have asserted itself among economists from the middle of the eighteenth century on. Why was it that economists took fright at a scarecrow! The first step toward a solution of this problem is to localize the emergence of the Malthusian attitude. German and Spanish economists were not afraid of the scarecrow. In fact there never was any native Malthusianism either in Germany or Spain: such Malthusianism as there ever was in those countries was the product of English teaching during the first half of the nineteenth century. The Italians, as stated above, had some real reason to be (mildly) frightened, and were. But the cradle of the genuinely anti-populationist doctrine was France. The second step toward a solution is therefore to find out whether there was not something in the economic and political situation of France that might, 'objective' opportunities notwithstanding, suggest pessimism as regards the economic future of the country and thus explain that change in attitude. As a matter of fact, there was. During practically the whole of the eighteenth century France was fighting a losing battle with England. Many of her leading spirits began to accept this defeat by 1760 and to discount the opportunities for national expansion. Moreover, the outworn institutional pattern of the last half century of the monarchy was not favorable to vigorous economic development at home. Thus, thought turned from bold venture to the possibilities offered by agriculture, from dreams of evolution to the picture of a 'mature' or quasi-stationary economy. The third and final step, then, is to explain why anti-populationist sentiment gained a hold on the English mind in spite of the fact that exactly the opposite state of things prevailed in England. In order to understand this we have to realize that the long-run trend of an evolution is one thing, and the sequence of short-run situations through which it fights its way is quite another thing. Thus, the English populationists of the seventeenth and eighteenth centuries may have been quite right in considering rapid increase as motor, condition, and symptom of economic development, and equally right in worrying at the same time, as most of them actually did, about the short-run vicissitudes, the unemployment in particular, which accompanied that development; this does not convict them of contradiction either in their analysis or in their recommendations. But in the Industrial Revolution of the last decades of the eighteenth century, these short-run vicissitudes grew more serious than they had been before, precisely because the pace of economic development quickened. And some economists—as will be pointed out in a moment, a minority only—were so impressed by them as to lose sight of the trend. The resulting anti-populationist mood then produced the set of analytic propositions that came to be known, in the nineteenth century, as the Malthusian principle or theory of population. Before considering its early history, we must attend to another matter.

[(b) *Growth of Factual Knowledge.*] In the United States the first census was taken in 1790; in England in 1801. In Canada and in some countries of continental Europe there had been earlier ones, but it was only in the first decades of the nineteenth century that reliable information about the numerical facts of population became available at regular intervals. The writers of the seventeenth and eighteenth centuries, therefore, theorized about population in ignorance of statistical facts. All they had to go on, if we except the rare cases in which local observation yielded definite results, were untrustworthy indications and vague impressions: thus, it was possible for English writers to disagree on such a question as whether the English population had increased or decreased during the century between 1650 and 1750. Hence, the investigations that were undertaken in order to dispel this fog and the resulting controversies exemplify a peculiar type of theory. Ordinarily, theoretical analysis is concerned with facts that are, or are supposed to be, known: it marshals, interprets, explains, establishes relations between, and generalizes from given facts or 'data.' This, of course, is also what the theory of population was to do in the nineteenth century. But in the seventeenth and eighteenth centuries, the main task of research on population was not to analyze given facts but, so far as possible, to find out what the facts actually were: it was the kind of theory that, unlike other kinds, retreats before advancing factual knowledge and must eventually be replaced by it. But the work done by those investigations—first by the Political Arithmeticians—also laid the foundations of the later theory of population. For many of the considerations that were originally developed in order to form an idea of the facts, served later on to interpret them. This is why examples of those controversies are presented below.

Sir William Petty's *Essay concerning the Multiplication of Mankind* (2nd ed. rev. and enl., 1686) is the standard example of seventeenth-century speculation about the facts. Sir Matthew Hale's *Primitive Origination of Mankind* (1677; partly republ. in 1782 under the title of *Essay on Population*; on the author see J. B. Williams, *Memoirs of the Life, Character and Writings of Sir Matthew Hale*, 1835) may also be mentioned. Both authors infer facts, on scanty observations, mainly from 'laws' derived from general considerations.

Of eighteenth-century controversies we shall first notice one that arose from Montesquieu's statement in the *Lettres persanes* that the ancient world was more populous than was the Western world of his time. In his essay 'Of the Populousness of Antient Nations' (*Political Discourses*, 1752), Hume proffered reasons for the opposite opinion that were criticized by Robert Wallace in the Appendix to his *Dissertation on the Numbers of Mankind* (1753), in which he upheld Montesquieu's thesis. Wallace found a follower in William Bell, who expanded the discussion on numbers into a discussion of causes and effects: in his dissertation *What Causes principally Contribute to Render a Country Populous?*

And what Effect has the Populousness of a Nation on its Trade? (1756) he presented the theory that the development of manufacture and trade, by diverting resources from the production of foodstuffs, tends to produce a decrease in population (which he took to be a fact and of which he disapproved); accordingly, he advocated fostering agriculture and an equal distribution of land among farm families. This tract called forth another, *A Vindication of Commerce and the Arts* (1758) by W. Temple (a clothier, not to be confused with Sir William Temple, the seventeenth-century statesman and writer). No great importance attaches to either Bell's or Temple's works. They are mentioned here because of a similar discussion on a similar subject that took place half a century later and is much better known: opinions not unlike those of Bell, having been reasserted by Thomas Spence, elicited a reply by James Mill that established his reputation as an economist.

Another controversy was more interesting. In 1779, Richard Price, now mainly remembered on account of his proposal to establish a sinking fund that would extinguish the national debt, published an *Essay on the Population of England* in which he stated that population had decreased by one-fourth since the revolution of 1688 and that urban agglomeration was responsible for it. Naturally this was attacked by a number of writers, especially by W. Wales (*An Inquiry into the Present State of Population in England and Wales*, 1781), John Howlett (*Examination of Dr. Price's Essay* . . . 1781), and others, A. Young among them. Howlett's contribution is the most interesting one, not only because it is a good example of the art of reasoning on inadequate facts but also because, like Bell, he launched out into an analysis of related economic phenomena. In particular, he interpreted enclosures as a consequence of the increase in population and as a 'cause' of some of those improvements in agriculture that were called for because of that increase —a theory in which there was an important element of truth.

[(c) *Emergence of the 'Malthusian' Principle.*] The theory of population as understood in the nineteenth century, however, that is to say, a theory of the factors—or 'laws'—that determine numbers and rates of increase or decrease, emerged much earlier than that.[3] Divested of nonessentials, the 'Malthusian' Principle of Population sprang fully developed from the brain of Botero in 1589: populations tend to increase, beyond any assignable limit, to the full extent made possible by human fecundity (the *virtus generativa* of the Latin translation); the means of subsistence, on the contrary, and the possibilities of increasing them (the *virtus nutritiva*) are definitely limited and therefore impose a limit on that increase, the only one there is; this limit asserts itself through want, which will induce people to refrain from marrying (Malthus' negative check, prudential check, 'moral restraint') unless numbers are periodically reduced by wars, pestilence, and so on (Malthus' positive check). This path-breaking performance—the only performance in the whole history of the theory of population to deserve any credit at all—came much before the time in which its message could have spread: it was practically lost in the populationist wave of the seventeenth century. But about two hundred years after Botero, Malthus really did no more than repeat it, except that he adopted particular mathematical laws for the operation of the *virtus generativa* and the *virtus nutritiva*: population was to increase 'in geometric ratio or progression'—that is, in a divergent geometric series—food in 'arithmetic ratio or progression.'[4] But the 'law of geometric progression,' though not in Botero's work, was suggested by Petty in his *Essay concerning the Multiplication of Mankind* (1686), by Süssmilch (1740), by R. Wallace (1753), and by Ortes (1774), so that, within this range of ideas, there was nothing left for Malthus to say that had not been said before. Of the eighteenth-century authors who, without committing themselves to this particular mathematical form, stated that population will always increase to the limit set by the supply of means of subsistence, it will suffice to mention Franklin[5] (1751), Mirabeau (1756)—who expressed himself in his picturesque manner: men will multiply to the limits of subsistence like 'rats in a barn'—Sir J. Steuart (1767), Chastellux (1772),[6] and Townsend (1786).[7] Steuart, whose priority Malthus was to acknowledge, was particularly explicit. Exactly as Botero did, he took the 'generative faculty' as a constant force to be compared to a spring that is held down by a weight and is certain to respond to any decrease in this weight. Townsend defined the limiting factor as 'hunger, not as directly felt or feared by the individual himself, but as foreseen and feared for his immediate offspring.' As far as I know, Ortes was the only writer to admit that 'reason' may have more influence than is implied in the anticipation of want—an influence that he illustrated by the celibacy of the Catholic clergy.

---

[3] See especially: René Gonnard, *Histoire des doctrines de la population* (1923); J. Bonar, *Theories of Population from Raleigh to Arthur Young* (1931); C. E. Stangeland, *Pre-Malthusian Doctrines of Population* (1904); J. J. Spengler, *French Predecessors of Malthus* . . . (1942); F. Virgilii, *Il Problema della popolazione* (1924). Readers are referred to these works for details of a story that cannot be presented here.

Botero, then, was the first to sound that note of pessimism which was to become so famous a bone of contention in the days of Malthus: as we have seen, he associated increase of population with actual or potential misery. But most of the authors who believed that populations tend to increase without assignable limit did not share Botero's pessimism but were on the contrary in sympathy with the populationist sentiments of their times and countries. Petty and, before their conversion to the Botero-Malthus view of he matter, Mirabeau and Paley may serve as examples.[8] This position involves, of course, no error of reasoning. For the fact that a population *is physically capable* of multiplying until it lacks not only food but also ground to stand on is no cause for worry unless complemented by the additional proposition that *it actually will* tend to do this instead of merely responding to an expanding economic environment by growing along with it (or even, possibly, by a decrease in the birth rate). In other words, population must actually tend to 'press against' the food supply. But even if such a tendency be admitted, it need not cause any worry about the calculable future or, what is more important for us, have any relevance to the explanation of contemporaneous phenomena. For this to be the case it is evidently not sufficient to believe that population will or may 'press against' food supply at some indefinitely distant time: we must believe the pressure to be either actually present or actually imminent. Unless this can be established, belief in that tendency is compatible with the opposite belief as regards any given situation or as regards the outlook *ex visu* of any given situation. The reader may well think that I am placing unnecessary emphasis upon these obvious distinctions, but their neglect is responsible for the futility of many of the controversies that arose about population both in the eighteenth and in the nineteenth centuries.

---

[4] If an initial value be denoted by a and another constant by b, then a geometric series runs like this: $a, ab, ab^2, ab^3, \ldots$ The series is divergent, i.e. the sum of its elements soars above any figure we care to name, if b is equal to, or greater than, unity. An arithmetic series runs like this: $a, a+b, a+2b, a+3b \ldots$ It is always divergent.

[5] Benjamin Franklin, *Observations concerning the Increase of Mankind*. Still more than others Franklin treated the case of human populations in the light of the general case of all animal species. On the other hand, he emphasized 'room' and 'enemies' as limiting factors rather than food.

[6] François Jean, Marquis de Chastellux, soldier by profession, published a treatise *De la félicité publique* that is not without merit.

[7] Joseph Townsend, see especially his *Dissertation on the Poor Laws*, 1786.

A work by R. Wallace[9] will, however, illustrate the way in which mere belief in pressure of population at some indefinitely remote future may after all be made relevant to economic analysis. Wallace considered equalitarian communism as the absolutely ideal form of society. Nevertheless, he rejected it. And the only reason he adduced for doing so was that in such a society there would be no check to the operation of mankind's physical powers of multiplication, so that the career of a communist society would eventually have to end in overcrowding and misery—a standpoint that evidently did not imply any opinion about the situation that actually prevailed in Wallace's time. Whatever we may think of the merits of the argument, it presents two characteristic features that cannot be underlined too strongly. First, if the proposition about unchecked multiplication were valid, it would evidently come near to being a 'natural law' in the strict sense of the term. Most of the English economists of the subsequent hundred years accepted it as such—as formulating an inexorable quasi-physical necessity. The same economists were in the habit of claiming similar necessity and universal validity, not only for those economic propositions that are nothing more than applied logic, but also for others such as their 'law of wages.' It is evidently not unreasonable to suspect that this habit of the English economists had something to do with their belief in that biological 'law.' If this be so, the question of the classic 'eternal laws of economics' should not be treated as a question of the philosophy of scientific method but simply as a question of the validity or relevance of an individual proposition. Second, it never seems to have occurred to Wallace to look for obstacles to human perfection other than mankind's power of multiplication: except for the dangers that threatened from this he had no more doubt about human perfectibility than had Condorcet. This was in keeping with the superficial sociology of the Enlightenment, but it is interesting to note that Malthus and in fact all the 'classics' seem to have been of the same opinion. I know of only one writer who at least sounded the eugenic note. It was Townsend. In the work mentioned above he argued that provision for the 'idle and vicious' would put a burden on the 'more prudent, careful, and industrious' that would restrain them from marrying: 'the farmer breeds only from the best of his cattle; but our laws choose rather to preserve the worst. . .'

---

[8] Petty listed populousness among the main assets of the Netherlands which made them such formidable competitors of England. Mirabeau, in those parts of *L'Ami des hommes ou traité de la population* that were published in 1756, declared that a large population is a blessing and the source of wealth: agriculture should be encouraged precisely because this would make people multiply like rats. It was Quesnay himself who induced Mirabeau to reverse the causal relation between wealth and population. William Paley (*Principles of Moral and Political Philosophy*, 1785, Book VI, ch. 11) held the same opinion. He was converted by Malthus' *Essay* and recanted in his *Natural Theology* (1802).

[9] *Various Prospects of Mankind, Nature, and Providence*, 1761. This work was criticized by Godwin and, since Malthus' work in turn started from a criticism of the latter's ideas, Wallace may have had more influence upon what became known as Malthusianism than any other of the writers who anticipated Malthus' doctrine. Malthus did full justice to Wallace's work but made it quite clear that, unlike Wallace and like Quesnay, he believed that pressure was an actual and indeed ever-present fact.

The outstanding authority for the other opinion, that is to say, for the opinion that pressure of population was actually present around 1750—and is in fact an ever-present phenomenon—was Quesnay. Unlike Cantillon, from whom he broke away in this point,[10] he held not only that propagation has no other limits than those of subsistence but also that it tends *always* to go beyond them. The only justification he proffered for this dogmatic statement was that, always and everywhere, there are people who live in poverty or want (*indigence*). This overpopulation theory of poverty is of the essence of 'Malthusianism.' But before the publication of Malthus' *Essay* it had so few adherents that to this day most historians attribute it to him. Populationism did not indeed hold its own—not, at least, outside Germany and Spain. But everywhere economists refused to accept the opposite view. Most of them seem to have agreed with Bishop Berkeley, who delighted in the vision of joyfully bustling multitudes, or with Hume, who called the happiness of society and its populousness 'necessary attendants.' Accordingly, A. Smith summed up by reducing the principle of population to a stale truism, preserving however its character as a natural law: 'every species of animals naturally multiplies in proportion to the means of their subsistence, and no species can ever multiply beyond it.'

---

[10] Substantially, Cantillon was populationist. But he touched in passing upon the problem 'whether it is better to have a great multitude of poor people or a smaller number of more prosperous ones.'

(*Wealth*, Book I, ch. 8.) And at the same time he declared, in the spirit of the old populationists, that 'the most decisive mark of the prosperity of any country is the increase of the number of its inhabitants' (ibid.). Beccaria discounted both the enthusiasms and the pessimisms of economists about increasing numbers: he recognized that increase was not always a blessing to be prayed for at all times; but also that there was no reason for being afraid of it at all times. In fact he seems to have been the one authority to teach explicitly the obviously sensible view. Genovesi went further than this, however, in effecting a synthesis between the two opposites. He saw that, from the standpoint of a population living under given conditions, numbers are capable of being either too small or too great in the sense that increase or decrease would produce greater 'happiness.' This led Genovesi to reassert the old idea of optimum population (*popolazione giusta, Lezioni*, Part I, ch. 5) that was to be sponsored again by Knut Wicksell. This concept is difficult to handle and perhaps not very valuable. But it has the merit of bringing out the truth that populationism and Malthusianism are not the mutually exclusive opposites they seemed to be to so many people.

2. INCREASING AND DECREASING RETURNS AND THE THEORY OF RENT

[(a) *Increasing Returns*.] We have seen that the populationist attitude, so far as it is economically motivated, implies a belief that increase in population will (within limits) increase per capita wealth or, as we may also put it, a belief in Increasing Returns. So does, in most cases, the protectionist attitude that went with populationism (see below, ch. 7). The idea of increasing returns in this sense—that is to say, increasing returns with reference to a national economy as a whole, and irrespective of any well-defined reason why returns should be increasing and of whether it is physical returns or returns in terms of money that are meant—is no doubt a hazy one and does not amount to more than an 'inkling' of any of the various meanings that the concept was to acquire. But beyond such inklings, which were of course very frequent, we also find here and there more precise arguments such as Petty's argument that expenditure on what may be termed social overhead—expenditure on government, roads, schools, and so on—does not, other things being equal, increase proportionately with population: this puts increasing returns into the not quite equivalent form of decreasing cost per unit of service, but nevertheless identifies a definite phenomenon that can be observed in every society and in every individual firm. Before this, a general law of increasing returns in manufacturing industry, also in the form of a law of decreasing unit cost, had been stated explicitly and in full awareness of its importance by Antonio Serra,[1] much as it was to be stated in the nineteenth-century textbook. The restriction of increasing returns to manufacturing should be particularly noticed. Serra did not indeed assert that agrarian production was subject to decreasing returns. But the idea that industrial and agrarian production as such follow different 'laws' was as clearly expressed by him as if he had. Thus he foreshadowed an important feature of nineteenth-century analysis that was not completely abandoned even by A. Marshall. In the seventeenth and eighteenth centuries, however, most economists said nothing about this. But many implied, or even explicitly said, that increasing returns prevailed also in agriculture. We shall presently discuss the most important example of this position. At the moment let us notice that A. Smith, more than a century and a half after Serra, took a view that was closely similar to his. He clearly, though loosely, stated a law of increasing returns for manufactures: first, in connection with division of labor (Book I, ch. 1) and, second and more fully, in the digression on the 'Effects of the Progress of Improvement upon the Real Price of Manufactures,' which he inserted into Part III of his huge chapter on the rent of land (Book I, ch. 11), where he attributed the fact that 'a much smaller quantity of labour becomes requisite for executing any particular piece of work' 'in consequence of better machinery, of greater dexterity, and of a more proper division and distribution of work.'[2] But nowhere did he state a law of decreasing returns, though he repeatedly brushed against it, especially in Chapter 11. In fact, in Chapter 1, he merely noted a difference between agricultural and industrial production in the scope they offer for ever increasing division of labor, and his text is compatible with the interpretation that he meant to assert increasing returns also for agriculture but to a lesser degree. And this in spite of the fact that the two cases of decreasing (physical) returns, which West and Ricardo were to recognize, had been fully described before him by Sir James Steuart (1767) and Turgot (1767).[3]

---

[1] *Breve trattato* (1613), Part I, ch. 3: *nell' artefici vi può essere moltiplicazione . . . e con minor proporzione di spesa* (in manufacturing industry, output may be increased at less than proportional increase in expense). Serra does not tell us to what this fall in cost is due. It may be plausibly assumed, however, that he thought of the same facts that A. Smith was to enumerate.

[(b) *Decreasing Returns: Steuart and Turgot.*] Steuart in his *Principles* (1767)—and after him Ortes in his *Economia Nazionale* (1774)—presented what the late followers of Ricardo were to call the case of the Extensive Margin: as population increases, poorer and poorer soils have to be taken into cultivation and, applied to these progressively poorer soils, equal amounts of productive effort produce progressively smaller harvests. Turgot discovered the other case of decreasing physical returns, the one that the same followers of Ricardo were to refer to as the case of the Intensive Margin: as equal quantities of capital (*avances*)—amounts of labor would, however, do just as well in this case—are successively applied to a given piece of land, the quantities of product that result from each application will first successively increase up to a certain point at which the ratio between increment of product and increment of capital will reach a maximum. Beyond this point, however, further application of equal quantities of capital will be attended by progressively smaller increases in product, and the sequence of these decreasing increases will in the end converge toward zero. This statement of what eventually came to be recognized as the genuine law of decreasing returns cannot be commended too highly. It embodies an achievement that is nothing short of brilliant and suffices in itself to place Turgot as a theorist high above A. Smith. It is much more correct than are most of the nineteenth-century formulations—Turgot's formulation was indeed not surpassed until Edgeworth[4] took the matter in hand.

---

[2] Observe that this statement mixes up two entirely different things: 'better' machinery seems to point to an effect of the widening of knowledge—the Technological Horizon—that occurs in the course of economic development. Improved division of labor, on the other hand, is one of the consequences of mere increase in output and may occur within an unchanging technological horizon or an unchanging state of the industrial arts.

[3] Observations *Sur le Mémoire de M. de Saint-Péravy*, included in the editions of the *Oeuvres* (mentioned in ch. 4, sec. 4). The date given in the text is not absolutely certain; moreover, it is the date of writing. We do not know how wide or narrow a circle of readers the paper reached at the time.

A particularly felicitous feature is the insertion of an interval of increasing returns before the interval of decreasing returns; that is to say, the recognition of the fact that decreasing returns do not prevail right from the application of the first 'dose' of some variable factor but set in only after a certain point has been reached. This should have disposed, once for all, of the erroneous opinion that he who asserts that extension of production will, under given circumstances, be attended by increasing returns therefore denies the validity of the 'law of decreasing returns.' Moreover, Turgot's increasing returns are defined with unsurpassable neatness: they are the increasing returns that attend the application of a variable factor to one that is given in a fixed quantity—or to a set of factors whose quantities are held constant—*before the optimum combination of factors is attained*. Thus, Turgot may be said to have formulated a special case of what American economists around 1900 were to call the Law of Variable Proportions.[5]

---

[4] See below, Part IV, ch. 6, sec. 5b.

[5] The same thing may be expressed, by means of a different concept, in a somewhat different way. This concept, which emerged toward the end of the nineteenth century (see below, Part IV, ch. 7, sec. 8), is now being called the Production Function. This function expresses the technological relation that exists between the quantity of product and the quantities of the 'factors' that co-operate in varying proportions to produce it. Reducing, for the sake of simplicity, the number of these factors to two, we may mark off the quantities of the product and of the two factors on the axes of a system of rectangular space co-ordinates. Every point in space that corresponds to any positive and finite values of those three quantities will then represent that quantity of product that can (at best) be produced by the corresponding quantities of factors, and the set of all these points will identify a surface in three-dimensional space, the production surface. Now let one of the factor quantities be held constant, and cut this surface by a plane at right angles to this factor's axis and go through the point on this axis that corresponds to the constant. The curve of intersection between the surface and the plane will represent Turgot's law of first increasing and then decreasing returns. Though Turgot did not discover either the production function or its geometric picture, the production surface as such, we may say that he discovered a property of it, viz., the form of one of its contours, and hence that he got hold of something, possession of which (with ordinary care and competence prevailing in our science) should

And finally it must be recorded to Turgot's credit that he stated his law in terms of successive increments of product and not in terms of average product (per unit of the variable factor). This means that he actually used marginal analysis and that command of modern technique could have improved only the form of his statement. There is really nothing to criticize in it except inadequate awareness of the necessity to specify both the product for which his law is to hold and also the variable factor that is to be applied: the basketful of disparate things that hide behind his *avances* does not meet the latter requirement but merely dodges it.[6] To the further objection that he did not emphasize the fact that his law made sense only with a given state of technological knowledge, or a given technological horizon, or a given production function—as we should say—he would probably have replied that this goes without saying. But we are about to see that this is not so. Another point must, however, be noticed before we go on.

Both Steuart and Turgot spoke of agriculture only. Fifty years ago this would not have astonished anybody, since it was then established practice to restrict decreasing returns to agriculture. But we who take it for granted that neither increasing nor decreasing returns are restricted to any particular branch of economic activity but may prevail in any branch, provided certain general conditions are fulfilled, are in a position to realize how surprising that actually was. Explanation seems to lie in the fact that, to the unsophisticated mind, there is something particularly compelling in the limitations imposed upon human activity by an inexorably 'given' physical environment. It takes prolonged effort to reduce the analytic importance of these limitations to their proper dimensions and to divorce them from the soil and the industry that works the soil. Yet it should not have taken so long to see that there is really no *logical* difference between trying to expand output on a given farm and trying to expand output in a given factory, and that if farms cannot be indefinitely multiplied or enlarged, neither can factories. The additional explanation required is provided by the belief of practically all eighteenth-century authors—a belief that carries over to the 'classics' of the nineteenth century—that while the factor land was given once for all, the other original factor, labor, would always increase to any amount required if allowed to do so. If we adopt this view, we shall at once sympathize with the reluctance of those authors to treat labor and land alike and to apply the laws of physical returns impartially to both. Then we shall also sympathize with the lopsided analytic structure they set up.

---

have brought out the production function of today before the eighteenth century was out. The reason why this argument is being inflicted upon the reader at this stage is that the case is so revelatory of the 'ways of the human mind,' which rarely discovers the obvious and fundamental first. More often it gets hold of some particular aspect of an idea and then works back to the conceptions that hold priority in logic.

[6] Unless the factor applied is such a definite physical thing as a fertilizer of invariant kind and quality or even labor of a given kind and quality, difficulties arise that threaten the meaning of the law.

[(c) *Historical Increasing Returns.*] As we have seen above, asserting that, in a given situation, increasing returns prevail in a country's agriculture, that is, that increase of input would be attended by more than proportional increase in output, does not imply denial of the validity of the law of decreasing returns. This fact must now be brought to bear upon the interpretation of the views of those English economists and politicians who actually did make that assertion. Whether right or wrong in point of fact, their position was logically defensible if they meant no more than either or both of two things. They were all right as to logic (though possibly wrong as to their facts) if they meant that in the last decades of the eighteenth century English agriculture [7] was moving in an interval of increasing returns, that is to say, that land had not yet received its optimum complement of other factors. They were not less right in logic (and, to some extent, in fact) if they meant that there were looming in the future possibilities of improving agricultural methods of production that would materialize if additional resources ('capital') were made available to agriculture—in the same way in which this was actually happening in industry. Observe, however, that this is something quite different from the increasing returns we have been discussing. We can indeed, if we so choose, speak of increasing returns' attending increased application of resources also in this case. But these spells of increasing returns, unlike the others, do not occur within the given pattern of technological practice. Like A. Smith's improved machines they involve a change in this pattern. If we visualize Turgot's intervals, first of increasing and then of decreasing returns, as a curve that ascends, reaches a maximum, and then descends,[8] then we see that the increasing returns in the previous sense are depicted by a section of the curve, but that increasing returns in the sense now under discussion are not. They can, however, be represented by shifting the whole curve upward (altering its shape or not as the case may require) into a new position: the old curve breaks off and is replaced by a new one that keeps a higher level (though not necessarily all along its course) but again displays both an interval of increasing returns in the previous sense and an interval of decreasing returns. The increase in returns in the new sense occurs as the curve shifts from its old to its new position. It should be added that, if the curve shifts again and again, there is no reason why the differences between these successive levels should grow smaller: *there is no law of decreasing returns to technological progress.* In order to avoid confusion between two entirely different phenomena, we had better restrict the term Increasing Returns to Turgot's case. This we shall accordingly do. When we wish to retain the association between the two, misleading though it is, we shall use, for the phenomenon now explained, the phrase Historical Increasing Returns. The phrase has been chosen in order to indicate that these historical increasing returns cannot, like the genuine ones, be represented by any curve or 'law,' least of all by a curve on which we can travel back and forth. For new levels of technique are reached in the course of an irreversible historical process and are hidden from us until they are actually reached.

---

[7] Those authors and politicians always spoke of returns to agriculture as a whole just as nineteenth-century economists were in the habit of doing. Strictly, however, the laws of returns in the sense of Turgot are defined only for the individual farm. It is an additional merit of Turgot that he so envisaged them. Transition to a whole industry, let alone the national economy as a whole, is not quite such plain sailing as primitive analysis assumes.

[8] See footnote 5 above. To repeat, the abscissae of the curve there described represent successive equal 'investments' of some resource, say, labor of a given quality, the ordinates the corresponding amounts of total product. But we may also let the ordinates represent the *increments* in total product that successively result from each additional dose of 'investment.' Of course, this 'derived' curve (of marginal products) will reach its maximum before the other does.

An example will illustrate this situation. One of the most interesting English economists of the late eighteenth century, Anderson,[9] boldly asserted that man's power to increase the productiveness of his fields was such 'as to make it keep pace with his population whatever that might be.'[10]

This has been interpreted to spell denial of the law of decreasing returns, Malthus being the first of Anderson's critics to misunderstand him in this sense. But Anderson's emphasis was not upon the *product* but upon the *productiveness* of land. And this, together with his reference to 'discoveries' which occurs in the same passage, should be sufficient proof that all he was thinking of was what we have just decided to dub Historical Increasing Returns. In Anderson's case, it is particularly easy to satisfy ourselves that his no doubt exaggerated ideas concerning these possibilities were compatible with the recognition of the law of decreasing returns. Though it is true that he nowhere mentioned Turgot's case, it is equally true that he accepted Sir James Steuart's case. For he actually invented the 'Ricardian' theory of rent which presupposes it.

[(d) *Rent of Land.*] We have seen that the explanation of the rent of land was not one of the problems that attracted attention in the early stages of economic analysis. Cantillon and, after him, the physiocrats, may be said to have been the first [11] to entertain a distinctive view of the phenomenon: it simply amounted to the proposition, if we may couch it in terms of a later time, that land yields rent because it is a scarce factor of production (or even the only 'original' one), and that this rent is partly an interest payment on investments made by the landlord and partly a payment for the 'natural and indestructible productive powers of the soil.' This theory was primitive and not fully articulate but nevertheless superior to many later speculations. In addition to the merit of saying or implying nothing that is definitely wrong, it had another one that raises it above triviality: whoever holds this theory thereby proves his awareness of the fact that productiveness and scarcity, in the case of a costless factor, are sufficient to account for its yielding a net return so that there is no point in looking for other explanatory circumstances. But this is precisely what most economists failed to realize, then, and throughout the first half of the nineteenth century. Accordingly, they engaged in speculations that produced, before the eighteenth century was out, both the theories of rent that were to prevail during the subsequent epoch (roughly to the last quarter of the nineteenth century). The one may be associated with the name of Adam Smith, the other with the name of James Anderson.

---

[9] James Anderson (1739-1808) was a Scottish gentleman farmer. His numerous writings are as important for an appreciation of the course of the corn-law controversy as they are for the history of economic analysis. The most important ones are: *Observations on the Means of exciting a Spirit of National Industry . . .* (1777); *An Enquiry into the Nature of the Corn Laws* (1777); and several essays in his 6 volumes of *Recreations in Agriculture, Natural History, Arts, and Miscellaneous Literature* (publ. 1799-1802). He had to an unusual degree what so many economists lack, Vision.

[10] *Recreations*, Vol. IV, p. 374; the passage has been quoted by Cannan, *A History of the Theories of Production and Distribution* (3d ed., 1917, p. 145), in order to prove that the law of decreasing returns was unknown to the agriculturalists of that time. It is of course beyond doubt that they were thoroughly confused about it and that, since Turgot's performance had passed unnoticed, professional and political opinions of the time sometimes read like unalloyed nonsense. But it should not be asserted without qualification that they actually were unalloyed nonsense or that they were always vitiated by the ignorance of that law.

A. Smith's theory of value, which will be discussed in the next chapter, yields the result that, under conditions of competition, a costless thing really cannot have a price. The services of land are costless: A. Smith explained at length that these services are not to be identified with the services of the capital that may have been invested in the land. Nevertheless, they fetch a price. Hence 'the rent of land . . . considered as the price paid for the use of land, is naturally a monopoly price' (*Wealth*, Book I, ch. 11). If this were true, rent would have to 'enter into the composition of the price of commodities' exactly as do profit and wages, which A. Smith explicitly denies on the next page. But of course it is not true: the landed interest is not a single seller and therefore its income cannot be explained by the theory of monopoly. The poverty of this rent analysis is overlaid by a plenty of materials and detailed comment that made the eleventh chapter burst the framework of Book I. Many of these details deserve recording but we must confine ourselves to three. First, A. Smith placed much emphasis upon the rent of location. Second, he worked out a theory that was to enter Malthus' stock in trade, and that kept on cropping up in the lower strata of the nineteenth-century theory, namely, the theory that 'Human food seems to be the only produce of land which always and necessarily affords some rent to the landlord' (ch. 11, Part II) because, by virtue of the principle of population, food production is the only kind of production which, as it were, will always create its own demand—mouths always increasing in response to every increase in the supply of food.

---

[11] This disregards the comments that Petty made on the subject—which do not amount to much—and also something else. Those authors who, like Locke, explained —or 'justified'—property in land by labor invested in it might be interpreted to have held a labor theory of rent. Such attributions are, however, unsafe and I prefer not to stress this point.

Though comment is, I trust, superfluous concerning the merits of this proposition, it is not superfluous to point out that this sort of thing goes far toward justifying the animosity to *theory* harbored by institutionalist and historical economists. It is for the same reason that I mention a third theory (presented in the Conclusion of ch. 11): believing that *every* increase in the real wealth of society tends, directly or indirectly, to raise the real rent of land, he concluded that the class interest of the landowners 'is strictly and inseparably connected with the general interest of society' so that, unlike 'those who live by profit,' landowners when speaking from the standpoint of their class interest 'never can mislead' the public in its search for measures that promote the general welfare. A truly unbelievable piece of reasoning—the premiss could be shown to be wrong from material and argument within the covers of the *Wealth*, and the conclusion would not follow even if the premiss were right.[12]

As has been stated, we need nothing beyond the productiveness and the scarcity of land in order to explain why there is such a thing as rent. Neither the fact to be explained nor the explaining facts have anything to do with decreasing returns. However, the association of rent with decreasing returns, which was to be one of the most characteristic features of the Ricardian system, was established by Anderson. In his *Observations* of 1777 he arrived at the conclusion that the rent of land is a premium paid for the privilege of cultivating soils that are more fertile than others, and in his *Enquiry* of the same year he formulated more precisely the conditions which Cannan stated established the formula: 'The rent paid in respect of any particular boll is equal to the difference between the expense of raising the most expensive boll raised and the expense of raising that boll,' explaining fully how the competition among farmers will secure exactly this amount for the landlord.[13] In a later essay, included in the *Recreations* (Vol. v), he presented another aspect of the same idea by saying that rent was a 'contrivance' for equalizing the profits on lands of different fertility—an emphasis upon the 'law of the average rate of profit' that makes him a forerunner of Ricardo in still another sense. Except for the claim that it explained rent, all this was quite correct so far as it went. But the achievement of anticipating a century's thought on this subject would have been a noteworthy one, even if all of it had been wrong.

---

[12] Reasoning such as this indicates certain limitations of a man's judgment once for all. But we are also within our rights to suspect such an argument of ideological bias, precisely because of the obviousness of its faults. Therefore, it is interesting to note that as a matter of fact A. Smith harbored an ideological bias *against* the landed interest (see below, ch. 6) so that no explanation can be derived on this line.

[13] I fail to understand why the late Professor Cannan, who quoted the passages (op. cit. pp. 371-3) should have thought it necessary to warn his readers that 'Anderson's anticipation of particular points in the Ricardian theory must not be mistaken for an anticipation of the whole theory.' It is true that Ricardo also noticed the Turgot case of decreasing returns. But his reasoning practically runs in terms of the Steuart case, just as does Anderson's. Like Anderson, moreover, Ricardo seems to have thought that there would be no rent if there were no decreasing returns, thus confusing the latter with scarcity of land. Hence, as far as the *theory* (to which Cannan specifically refers) is concerned—and not the diagnosis of the actual conditions of English agriculture or the political recommendation—I cannot see any difference whatsoever between Anderson and Ricardo, or, for that matter between Anderson and West.

3. WAGES [1]

The most obvious analytic use to which the principle of population can be put is surely the theory of wages. Many writers—among the leaders, especially Quesnay and Turgot—might be cited to show how easy it was, starting from an uncritical acceptance of that principle, to arrive at a minimum-of-existence theory of wages as an equally uncritical conclusion. Since, moreover, the physiocrat theory of capital—the idea of the *avances*—was of a nature to suggest the concept of a 'wage fund,' another pillar of Ricardian economics was thus erected by pre-Smithian writers, mainly French.

But the proposition that wages per head tend toward a minimum-of-existence level (however defined) is no more a theory of wages than the quantity theory is a theory of money. Both are propositions about the values certain economic quantities assume in a state of long-run equilibrium and form part of a comprehensive theory of wages or money—that is, if we believe in them—but are not the whole of it. No such comprehensive theory was worked out before A. Smith. But many pre-Smithian economists contributed fragments. The most important of these contributions was Child's, discussed above in Chapter 4. It had nothing to do with the principle of population. Child, as we know, was a populationist who declared that 'most nations in the civilized parts of the world are more or less rich or poor proportionable to the paucity or plenty of people.' This paucity or plenty he made dependent upon 'employment,' so that we may interpret him to have meant that the wage rate is determined, on the one hand, by the demand for labor and, on the other hand, by the supply that this demand calls forth. This was a good beginning, the more so because Child said nothing about the particular level at which the forces of demand and supply would fix wages. In particular, he kept clear of any minimum-of-existence law. Instead, he said that high wage rates are the consequence and 'infallible evidence' of the riches of a country. Davenant went a little further in his statement that in a poor country interest is high and land and labor cheap. Also other writers got as far as this. But nowhere do we find more than this until we reach the minimum-of-existence theorists mentioned above.

This does not mean, of course, that people were not interested in wage questions. On the contrary, economists debated them eagerly and practically every one of them left us his opinion about wage policy. But most of these utterances were preanalytic in nature. They reveal sentiments and evaluations that reflect important aspects of social history and are a legitimate object for the application of the Marxist theory of ideology, provided that it be handled without unintelligent dogmatism. For us, however, these sentiments mean only an additional difficulty of interpretation: we are driven to unraveling elements of analysis from the various recommendations of our authors—or such reasons as they give for their normative statements—and in doing so we are in constant danger of mistaking for an analytic proposition what may have been no more than a profession of sympathies. Thus Child, though he interpreted high wages as a symptom of wealth, did not proffer any high-wage theory in the sense that high wages are in themselves a factor that makes for prosperity. But he was evidently in sympathy with high wages and hence *seems* to have held a high-wage theory in this sense. That this was not the case we can see from the way in which he behaved when confronted with a low-wage argument. He did not really argue but simply got angry and hurled defiance at the obnoxious doctrine: 'a charitable project and well becoming a userer!' Other authors offer hints at motivating analytic propositions. Some—including Cary—looked upon high wages as a part in the mechanism of brisk business and adumbrated the purchasing-power argument. Others were of the opinion that high real wages are conducive to better performance.[2] But this did not amount to much. Neither did the reasoning of the low-wage men. Petty's argument was that high wages would only encourage sloth and that if wages were doubled the supply of labor hours would be reduced to half. The most important argument on this side of the question was, of course, the argument from competition in international trade. It was because high wages would impair the competitive situation of the country that Sir James Steuart held that wages 'should' be kept at the level of physical necessities.[3] D. Hume also believed that high wage rates are detrimental to a country's foreign trade, though he did not draw the same conclusion; on the contrary, he went on to say that this disadvantage weighs lightly as compared with 'the happiness of so many millions.'

---

[1] The works on the history of population doctrines all take some account of the history of wage doctrines as well, but Spengler's should be particularly mentioned. Facts as well as views the reader finds in Heckscher and Mantoux. Also, see E. S. Furniss, *The Position of the Laborer in a System of Nationalism* (1920), which work, however, concentrates on the task of bringing out one particular aspect of the picture and does not aim at presenting the whole; and R. Picard, 'Étude sur quelques théories du salaire au XVIIIe siècle' in *Revue d'histoire des doctrines économiques* (1910).

---

[2] For example, Daniel Defoe (c. 1659-1731) in *Plan of the English Commerce* (1728); B. Franklin, in his *Reflections on the Augmentation of Wages*, also distinguished high wages from high cost of labor per unit of product.

[3] There cannot be any doubt, of course, that many declarations in favor of low wages simply and naïvely voice class interest and are not the result of any attempt at appraising causes and consequences in a scientific spirit. Not only did low-wage opinions fit the social structure and the resulting national spirit of those times, but also whatever low wage opinions were held were quite freely uttered because the labor interest was not yet a political factor and intellectuals therefore did not side with it. So opinions were held with regard to labor—and voiced without inhibitions—that sometimes recall the opinions held by the Romans with regard to their slaves as voiced, e.g., by Cato. That the welfare of the laborers, or 'laboring poor,' or simply the poor, should have been, by implication, denied the status of an end in itself—in the economic literature roughly until Beccaria and Smith—does not necessarily mean what it seems to mean. For such statements also occur with respect to the merchant class and are only what we should expect in a nationalist civilization. But opinions could be cited to the effect that workmen 'should' be kept poor, and ignorant as well as poor, that they 'should' be strictly disciplined and, in order to facilitate this, kept at work from early youth and continually, so that they should never know what it is to be at leisure and so on. Such views, like the opposite ones, naturally tended

A. Smith's performance in the field of labor economics[4] is highly characteristic and in fact a fair sample of his work as a whole. Moreover it acquires additional importance by virtue of its having been the first fully systematic treatment of the subject. He no doubt followed the available leads but, sealing off edges here and developing there, he made a well-rounded whole of it that was qualified to serve, as in fact it did serve, as a basis of further analysis. First of all, he worked out a comprehensive theory of wages. Borrowing a natural-law proposition that was widely accepted in his time, namely, that 'the produce of labour constitutes the natural recompense or wages of labour,' he proceeded to explain how it came to pass that labor has to surrender part of 'its' product—meaning the entire result of the productive process—to landlords and another part to 'masters.' Observe that this indeed posits the fundamental problem of wages but that it does so in a peculiar way: A. Smith's argument starts from a pseudo-historic background of a natural state in which, on the one hand, there are no landlords and no 'masters' and in which, on the other hand, labor is the only scarce factor of production; confusing these two quite different facts, he reduced the problem of wages at once to the problem of the two other distributive shares which thereby became 'deductions from the produce of labour.' Rent is a deduction from 'natural' wages that is motivated not by the productivity of land but by the emergence of private property in it which tallies nicely with his monopoly theory of rent: some people monopolize land exactly as they might monopolize air, were it technologically possible to do so. And profit is another deduction motivated not by the productivity of capital—stock 'advanced' to the laborer—but solely by the power of its owners[5] to insist on it, a power that is much enhanced by the ease with which these owners can combine against the poor and helpless laborers who 'must either starve or frighten their masters into an immediate compliance with their demands.' The reader should realize both the obvious weaknesses that this argument presents when considered as a piece of analysis and the appeal it was bound to have. It foreshadowed, in fact, all the exploitation and bargaining-power theories of wages that the nineteenth

---

to reflect themselves in the analytic work emanating from their sponsors or in the way in which its results are formulated: and if that analytic work is rudimentary, it becomes still more difficult than it is in the case of elaborate theories, to separate what for brevity's sake we may call the logic and the class interest served by that logic. This political aspect is also important for the topics to be touched upon in sec. 4, which follows.

[4] The substance of it is to be found in chs 8 and 10 of Book I of the *Wealth of Nations*. But additional facts and comments are scattered all over the work.

[5] It is only here, within the theory of wages, that A. Smith adopts this view. Elsewhere he leaves room for other elements, such as risk and trouble.

century was to produce, and also suggested the idea that labor is the 'residual claimant.'

A. Smith went much further than that, however. Since the laborer cannot live without the advances of the 'masters,' the latter can, strictly speaking, reduce his wages to the physical minimum of existence. But the masters' competition for labor will, with increasing national wealth, force them to 'break through the natural combination of masters not to raise wages' and will raise wage rates above that level for indefinite periods of time. Accordingly, A. Smith denied vigorously that wages in Great Britain were anywhere near the minimum-of-existence level or that they fluctuated with the price of provision as they would have had to do in that case.[6] For practical purposes this amounts to denying the validity of the physiocrat theory of wages. In principle, however, A. Smith accepted it. This reconciliation of two apparently contradictory opinions he achieved by emphasizing not so much the absolute level of the wealth from which the demand for labor proceeds but 'its continual increase' —it was not great wealth as such but increasing wealth which, outstripping increase in population, causes wage rates to rise in monetary as well as real terms. But wealth that does not increase, however great it may be, is no guarantee against low wages: the hands will 'in this case naturally multiply beyond their employment,' so that Quesnay would be right in the end. A. Smith also accepted the wage-fund theory, which he restated in the form that was to be the object of both elaboration and attack in the nineteenth century. When dealing with the demand for labor, he stated what reads like a harmless truism: this demand 'it is evident, cannot increase but in proportion to the increase in the funds which are destined for the payment of wages.' The joker that lurks behind the word 'destined' was responsible for many a headache later on. But A. Smith lightheartedly concluded that the demand for labor, since it comes either from the income of the well-to-do, who demand personal service, or from the stock of businessmen, who demand productive services, and since 'the increase of revenue and stock is the increase of national wealth,' will increase with the increase of wealth, 'and cannot possibly increase without it.' There is no more fertile source of error than apparently trivial premisses.

This theory of wages was copiously illustrated by all sorts of facts, which is why it gives the reader the impression of fullness and realism. Critical—and often wise—comments on the labor legislation and the poor laws of that and earlier times are freely inserted. And A. Smith's interest in the concrete phenomena of practical life is responsible for many analyses of particular questions, one of which may be mentioned. Abstract theory reasons about an imaginary wage rate, the counterpart of which in real life is a structure of widely varying wage rates. In order to make sure that a theory working with a single rate has any relevance at all to the explanation of real phenomena, we must analyze the nature of the differences in the wages—and profits—earned in different employments and places. This is the kind of thing in which A. Smith both delighted and excelled. The lead had been given by Cantillon. But A. Smith went much more deeply into the matter, thus creating an important if not exactly exciting chapter of the nineteenth-century textbook.

---

[6] This seems, however, to have been the prevalent popular opinion. Galiani in his *Dialogues* (see below, ch. 6) attributes it to *Le Marquis* whose role it is to voice popular opinions.

4. Unemployment and the 'State of the Poor'

In principle, medieval society provided a berth for everyone whom it recognized as a member: its structural design excluded unemployment and destitution. Actually, the threat of involuntary unemployment was not completely absent. The journeymen who worked under the masters within the craft guilds were often, and the agricultural laborers (*mercenarii*) were always, hired workers whose employment was not guaranteed. But as a rule neither group had much difficulty in finding jobs. In normal times unemployment was quantitatively unimportant and confined to individuals who had broken loose from their environment or had been cast off by it and who in consequence had become beggars, vagrants, and highwaymen. The highwaymen were treated with brutal yet ineffective energy; with the other types, the charity enjoined and organized by the Catholic Church was perfectly able to cope. It is important to keep this pattern in mind because it formed an attitude toward unemployment and the unemployed that persisted for centuries after medieval conditions had passed away. Let us remember in particular that mass unemployment, definitely unconnected with any personal shortcomings of the unemployed, was unknown to the Middle Ages except as a consequence of social catastrophes such as devastation by wars, feuds, and plagues.

This changed in and after the fifteenth century. The breaking up of the medieval world, attended as it was by social upheavals, is in itself sufficient to account for the widespread suffering and destitution we observe. The agrarian revolution not only destroyed environments that might have sheltered fugitives from distressed areas but also caused the landless proletariat to increase more rapidly than did the effective demand for labor. The resistance to change offered by the organized crafts, while it protected some elements of the population, made things worse for others. The rising capitalist industry in the long run absorbed rather than created unemployment. But there were many bottlenecks that impeded the development of the new opportunities and the flow of labor into them. Moreover, when the pace of industrial development quickened in the second half of the eighteenth century, technological unemployment put in an appearance as a mass phenomenon and frequently overshadowed that long-run effect. This explains why the rise of the factory system was associated with so much misery: for many years labor was not attracted to the factories by higher wages and better living conditions, but driven into them in spite of lower real incomes and worse living conditions. The old protective regulations broke down not so much under the influence of laissez-faire philosophies as under the weight of actual or threatening unemployment. For a time, though not everywhere to the same extent, all barriers to the deterioration of the worker's lot were giving way. Thus it is not difficult to understand the paradox already noticed, namely, that governments and writers who were enthusiastically populationist never ceased to worry about how 'to set the poor to work' or how to combat 'idleness.'[1]

But the first problem that confronted European governments from the beginning of the sixteenth century was an administrative one. Everywhere the swelling numbers of destitute beggars and vagrants outgrew the possibilities of private charity and everywhere public organization of relief had to take its place. In England, earlier measures were systemized by the Elizabethan Poor Law of 1601, which definitely established the compulsory poor rate on a permanent basis. The poor rate was a tax that was levied in every parish for the maintenance of its own destitute inhabitants. The burden was considerable and above all very visible. Principles and results were evidently debatable. Accordingly, amendments were suggested, discussed, and actually enacted in an unending stream until the advent of modern security legislation. Because of the importance for the history of economics of the corresponding stream of books, pamphlets, and articles which for more than three hundred years were to deal with those problems, we had better note the two main questions at issue. The Elizabethan enactment had left the administration of the funds raised by the poor rate to honorary local officers elected for the purpose, a highly inefficient arrangement which was not radically changed until the Poor Law Amendment Act of 1834; thus the first question was one of central versus local control. The second question, which is more interesting from our standpoint, was Outdoor Relief versus Maintenance in a Workhouse. Outdoor relief was the original method which, owing to a variety of administrative abuses that were only in part inherent in its principles, elicited the criticisms that brought the workhouse method steadily to the fore, and thus prepared the ground for its temporary victory in 1834.[2] To repeat, legislation and administration in the seventeenth and eighteenth centuries did little to supplement existing systems of unemployment relief by measures for the protection of the employed with respect to hours, working conditions, and so on (not even in the case of women and children). In some continental countries we find the beginnings of factory legislation within our period, in Austria, for instance, under the reign (1781-90) of Joseph II. But in England there was next to nothing before the (ineffective) Health and Morals of Apprentices Act of

---

[1] Those conditions have been described numberless times with widely varying degrees of competence and accuracy. Reference to the works of Heckscher and Mantoux must again suffice for our purpose.

[2] The reader will find a sufficiency of relevant facts in almost any economic history. Three books, however, should be particularly recommended: E. M. Hampson, *The Treatment of Poverty in Cambridgeshire, 1597-1834* (1934); S. and B. Webb, *English Poor Law History* (1927-9); and Dorothy Marshall, *The English Poor in the Eighteenth Century* (1926). An eighteenth-century history will be mentioned presently. The outstanding nineteenth-century history is Sir George Nicholls' *History of the English Poor Law* (1854), complemented by his histories of the Irish and the Scotch Poor Law (1856).

1802.[3] In another line, however, we may note the Friendly Society Act of 1793, which mitigated the legislation against corporative action by the workers.

The chief remedies for unemployment consisted in measures intended to foster manufacturing industry. We shall see later (in ch. 7) that concern about employment opportunity was one of the chief motives of 'mercantilist' policies. In some continental countries, especially in Germany, protection of the peasant holding was an important safeguard against pauperization of the industrial workers. And the deficit financing of continental governments, though not motivated by this purpose, certainly had some alleviating effects. England came much nearer to balancing her budgets. But some English writers, though they did not recommend deficits, were more alive to the possibilities of monetary remedies for unemployment than were their continental brethren.[4]

The late scholastics,[5] like their predecessors, had emphasized the role of charity and defended the beggar against the rough reactions of the environment. In particular, they had defended the 'right to beg.' But they came to realize that unemployment was growing beyond the possibilities of private benevolence and therefore entered upon a discussion of the possibilities offered by legislation and public administration, touching, first incidentally, later on more systematically, upon problems of causation. This discussion was taken up by laic writers, mainly the Consultant Administrators, all over Europe. In Germany, *das Armenwesen* naturally became a standard subject within the 'cameralist' literature. German governments accepted the state's responsibility for employment and maintenance as a matter of course. The same principle was repeatedly asserted in England, for example, by the Berkshire magistrates in 1795. But there is not much to record for the historian of economic analysis.[6]

In the first place, a great many writers on the poor laws argued on the explicit or implicit 'theory' that, barring misfortune, and especially sickness, the destitute unemployed was personally to blame for his fate. In appraising this view, contempt for its inadequacy as a theory of the social phenomenon to be explained, and indignation at the callousness of which it may be the symptom, must not blind us to the element of truth in it which has come to be as much underrated in our own time as it was overrated then. It was at the basis of the argument of the defenders of the workhouse system and survived, in various nuances, until 1914. The principles that relief should be confined to maintenance in the workhouse and that life and labor in the workhouse should be made less eligible than the least eligible employment may merely aim at testing the presence of destitution; actually, however, they were often associated with punitive intent that can be explained only on the theory in question. In the second place, writers who went beyond this mentioned a number of factors that were all of them more or less relevant to the explanation of either unemployment or substandard conditions among employed workers but without subjecting them to any elaborate analysis. The most important ones were foreign competition, high rates of interest, taxes and regulations that hampered enterprise, enclosures, and, mainly in connection with enclosures, property in land. It is very difficult to tell how much insight any such statement reveals. To mention one example, Child listed high interest as a cause of unemployment. But the reason he adduced was not that high interest may restrict investment but that it facilitates premature retirement from business, which, though not quite indefensible, looks very much like an analytic blunder. Machinery as a cause of unemployment (or of low wage rates) was mentioned with increasing frequency as the eighteenth century wore on. But nobody attempted to develop a theory of the mechanization of the productive process. On the whole, the opposite view prevailed, namely, that the introduction of machinery tends to increase employment and to raise wages. This opinion, already held by Cary, seems to have been shared by A. Smith. In the third place, during the last quarter of the eighteenth century a tendency asserted itself to explain unemployment by means of the 'principle of population.' The analytic nature of this line of reasoning can be best conveyed by an analogy. One of the familiar phenomena we observe in every depression is that producers cannot sell their wares at prices that will cover cost; hence nothing is easier than to jump at the conclusion that the root of the trouble is 'overproduction.' This is the most primitive of all theories of crises or depressions. And the most primitive of all theories of unemployment is that people cannot find work at living wages because there are too many of them. It was almost always at the bottom of arguments to the effect that more generous provision for the 'able-bodied poor' would make matters worse for the working class as a whole, or even that the poor law as it then stood was breeding poverty by fostering increase in population.[7] Observe that this theory, as far as there is anything to it at all, applies equally well to the relief granted to unemployed persons, and to the subsidies that the poor-law authorities were in the habit of granting to persons employed at less than living wages. The latter practice was severely criticized on account of the administrative abuses to which it gave rise—it made it possible for local potentates to shift part of their wage bill on to the poor rate. This is probably the reason nobody produced anything that could pass for a tolerably adequate theory of wage subsidies. But the fundamental similarity between unemployment and employment at substandard conditions stood out all the more clearly. Both entered into the concept of 'poverty' or 'indigence,' which, as we know, Quesnay had been the first to explain by overpopulation.

---

[3] See, e.g., B. L. Hutchins and A. Harrison, *History of Factory Legislation* (1903).

[4] The question how far economists of the seventeenth and eighteenth centuries may be credited with what we should call a monetary theory of employment will be briefly considered in the next chapter.

[5] The tracts by de Soto and de Medina (sixteenth century) mentioned already (see above, ch. 2), may again serve as examples from a large literature which continued to pour forth, especially in Spain and Italy, throughout the seventeenth and eighteenth centuries. We confine ourselves to noticing one of its latest and most successful products, Giovanni Battista Vasco's (1733-96) *Mémoire sur les causes de la mendicité et sur les moyens de la supprimer*, 1790 (republ., with other works of his, in the Custodi collection). Vasco was a Piedmontese priest who, under the influence of Turgot and A. Smith, developed into a thoroughgoing 'liberal' in the laissez-faire sense.

[6] For further information, see especially T. E. Gregory, 'The Economics of Employment in England, 1660-1713.' *Economica*, 1921. There is no equally valuable survey for any other country. Reference should, however, be made to the interesting article by G. Arias on Ortes' theory of unemployment, *Giornale degli Economisti*, September 1908.

---

[7] Such arguments were freely and effectively used against the legislation proposed by William Pitt which would have favored large families. The outstanding performance in this discussion was Jeremy Bentham's *Observations on the Poor Bill . . . [of] Mr. Pitt* (1797), which foreshadowed the opinion of the 'classical' economists of the nineteenth century on what, speaking from their standpoint, we might describe as the Fallacy of Relief. See *Works*, vol. VIII.

The discussion on the related problem of child labor was still less productive of analytic performance. Children had always worked with their parents on the farm and, under the system of domestic industry, in the home. The spread of factories merely created new opportunities for the employment of children at a very early age in the tending of simple machines and induced a new practice of binding out the children of paupers to cotton manufacturers in order to reduce the poor rate. Those writers who were impressed by the incidental horrors or by the obvious consequences for the health of the race were few indeed. The large majority accepted child labor, not only as a matter of course but with approval—as a sound discipline and as a solution of many of the worker's problems. Some seventeenth-century writers hailed it as a boon to the masses and seem to have considered the children's earnings as a net addition to the family income of workers, without taking account of the effects that the competition of the children must produce on the wages of adults. This theory, which was held by Yarranton,[8] qualifies well as an example of ideological distortion of vision. But it also qualifies as an example of early economic reasoning that in spite of its crudity contained an element of truth. If we choose to disregard everything except money income, then it is likely that in the conditions of that time child labor did result in a gain to the working class—though this gain was certainly less than the amount of the children's earnings—and did promote Yarranton's ideal of cheapness and plenty. This attitude changed but slowly in the eighteenth century, and humanitarian feelings had more to do with it than had economic analysis. Many instances could be adduced of writers who mention full employment of children at as early an age as possible—at six or even four years—with unqualified satisfaction; or who at least accepted it unquestioningly as the normal state of things.[9] Arthur Young's estimates of the normal budget of a rural laborer's family take it for granted that the chief breadwinner could not have provided a minimum of existence for his family without the earnings of his wife and children.

---

[8] Andrew Yarranton (1616-84), *England's Improvement by Sea and Land* (1677). Both the man and the book we shall meet again in ch. 7. It is of some interest to note that in his advocacy of extensive employment of children Yarranton pointed to German practice as an example to be followed.

[9] To quote at least one instance, in his *Tour thro' . . . Great Britain* (1724-7), vol. III, Daniel Defoe noted that in some English villages through which he traveled there were no children to be seen—inferring with pleasure that they were all at work as they should be. The same attitude is in evidence in his *Plan of the English Commerce* (1728).

But fact-finding activity was in a much better situation, and its results constitute, in the field of labor economics, the most important achievement of that epoch. The outstanding performance was Eden's,[10] which in scope and method has no equal in the English or any other literature of the period. Of particular interest for us is the fact that the author, although he disclaimed any intention beyond what fact-finding implies (he offers some interesting discussions, nevertheless), was fully aware of the importance of his facts, not only for the purpose of legislative and administrative practice but also for economic analysis. He worked, as he said himself, as one of the 'hewers of stone and drawers of water' without whom 'the edifice of political knowledge cannot be reared.' It is of the utmost importance to bear in mind, if the history of economics is to be understood, that, though the greatest figure, he was not alone in that field. Davies' collection of family budgets of agricultural laborers and his careful analysis of his data were conceived in the same spirit,[11] and so was Richard Burn's *History of the Poor Laws*, 1764. Work of this type paved the way toward the legislative developments of the nineteenth century.

[10] Sir Frederick Morton Eden (1766-1809), *The State of the Poor: or an History of the Labouring Classes in England from the Conquest to the Present Period; in which are particularly considered their Domestic Economy . . . ; and the various Plans which, from time to time, have been proposed and adopted for the Relief of the Poor . . .* (3 vols., 1797; abridged ed. by A. G. L. Rogers, 1928). The price and wage data and the budget study in the third volume are particularly important.

[11] David Davies, *The Case of Labourers in Husbandry stated and considered, in three Parts: Part* I. *A View of their Distressed Condition. Part* II. *The Principal Causes of their Growing Distress and Number . . . Part* III. *Means of Relief Proposed.* The budgets are given in the Appendix. The work was (partially) published in 1795.

A few more titles of English books that are of some interest from either the factual or the analytic standpoint may serve as pointers for the interested reader. Their choice must be understood, however, to be the result of very unsystematic browsing: L. Lee, *Remonstrance . . . touching the Insupportable Miseries of the Poore of the Land* (1644)—a scheme of re-employment by means of semipublic workshops; Roger North, *A Discourse of the Poor . . .* (1753); Anon., *Observations on the Number and Misery of the Poor . . .* (1765); Anon., *Observations on the Present State of the Poor of Sheffield . . .* (1774); Anon. [R. Potter], *Observations on the Poor Laws, on the Present State of the Poor, and on Houses of Industry* (1775). John Howlett's (see above, sec. 1) interesting argument concerning enclosures should be particularly noticed: *Enquiry into the Influence which Enclosures have had upon the Population of this Kingdom*, 1786, and *The Insufficiency of the Causes to which the Increase of our Poor and of the Poor's Rates have been Commonly Ascribed* (1788).

1. REAL ANALYSIS AND MONETARY ANALYSIS

WE HAVE already touched upon this subject in Chapter 4 when discussing Quesnay's work. It is now time to go a little more deeply into it in order to visualize as clearly as we can a doctrinal development that has acquired additional interest for the student of modern economics owing to the fact that Monetary Analysis has once more conquered in our own time. Let us first of all re-define the meaning of these two approaches.

---

[1] [Although this chapter was apparently written rather early, it was unfinished and not typed at the death of J. A. S. The manuscript pages were unnumbered and sometimes there were two or three versions of the same page. This chapter was put together with the assistance of Arthur W. Marget.]

Real Analysis[2] proceeds from the principle that all the essential phenomena of economic life are capable of being described in terms of goods and services, of decisions about them, and of relations between them. Money enters the picture only in the modest role of a technical device that has been adopted in order to facilitate transactions. This device can no doubt get out of order, and if it does it will indeed produce phenomena that are specifically attributable to its *modus operandi*. But so long as it functions normally, it does not affect the economic process, which behaves in the same way as it would in a barter economy: this is essentially what the concept of Neutral Money implies. Thus, money has been called a 'garb' or 'veil' of the things that really matter, both to households or firms in their everyday practice and to the analyst who observes them. Not only *can* it be discarded whenever we are analyzing the fundamental features of the economic process but it *must* be discarded just as a veil must be drawn aside if we are to see the face behind it. Accordingly, money prices must give way to the exchange ratios between the commodities that are the really important thing 'behind' money prices; income formation must be looked upon as an exchange of, say, labor and physical means of subsistence; saving and investment must be interpreted to mean saving of some real factors of production and their conversion into real capital goods, such as buildings, machines, raw materials; and, though 'in the form of money,' it is these physical capital goods that are 'really' lent when an industrial borrower arranges for a loan. The specifically monetary problems can then be treated separately, much as we treat many other things separately, for example, insurance.

Monetary Analysis, in the first place, spells denial of the proposition that, with the exception of what may be called monetary disorders, the element of money is of secondary importance in the explanation of the economic process of reality. We need, in fact, only observe the course of events during and after the California gold discoveries to satisfy ourselves that these discoveries were responsible for a great deal more than a change in the significance of the unit in which values are expressed. Nor have we any difficulty in realizing—as did A. Smith—that the development of an efficient banking system may make a lot of difference to the development of a country's wealth. To some extent, these and other things can be, and have been, recognized within the pale of Real Analysis. We may even hold monetary theories of business cycles or of interest without leaving its precincts. The reader should observe, however, that one cannot go very far on this route without becoming aware of the fact that the monetary processes that account for conspicuous 'disturbances' do not cease to act in even the most normal course of economic life. We are thus led, step by step, to admit monetary elements into Real Analysis and to doubt that money can *ever* be 'neutral' in any meaningful sense. In the second place, then, Monetary Analysis introduces the element of money on the very ground floor of our analytic structure and abandons the idea that all essential features of economic life can be represented by a barter-economy model. Money prices, money incomes, and saving and investment decisions bearing upon these money incomes, no longer appear as expressions—sometimes convenient, sometimes misleading, but always nonessential—of quantities of commodities and services and of exchange ratios between them: they acquire a life and an importance of their own, and it has to be recognized that essential features of the capitalist process may depend upon the 'veil' and that the 'face behind it' is incomplete without it. It should be stated once for all that as a matter of fact this is almost universally recognized by modern economists, at least in principle, and that, taken in this sense, Monetary Analysis has established itself.

---

[2] The phrase is not very felicitous. In particular, it invites confusion with another of the many meanings of the word 'real.' Real Analysis stands for emphasis upon real in the sense of non monetary processes. But we commonly use the word 'real' for monetary quantities that have been 'corrected' for changes in some price level. For instance, we speak of real income when we mean money income divided by a cost of living index. Such 'corrected' monetary quantities are, however, still monetary quantities and are, along with uncorrected ones, used also in Monetary Analysis. Therefore our distinction must not be identified with the distinction between analysis in terms of dollars of constant purchasing power and analysis in terms of 'current' dollars. Moreover, we are defining both Real and Monetary Analysis as pure types in order to convey an important truth. In actual practice, neither type is ever pure. Hence the contrast between them is less sharp than we are forced to make it. There are many midway houses. And neither Real nor Monetary Analysis can ever get along without using concepts and arguments that strictly speaking belong to the other. Sponsors of Real Analysis have often used a monetary capital concept; sponsors of Monetary Analysis always use the essentially 'real' concept, Employment.

[(a) *Relation of Monetary Analysis to Aggregative or Macroanalysis.*] Monetary Analysis, as usually understood, means more than this: in the third place, it means in addition Aggregative Analysis or, as it is sometimes called, Macroanalysis,[3] that is to say, analysis that attempts to reduce the variables of the economic system to a small number of social aggregates, such as total income, total consumption, total investment, and the like. Quesnay's *tableau* is the outstanding example for the alliance between Monetary and Aggregative Analysis. The alliance is not a logical necessity but is nevertheless close: it is possible, as we have put it, to introduce money on the ground floor of general economic analysis without adopting the aggregative view. But monetary aggregates are homogeneous, whereas most nonmonetary ones are but meaningless heaps of hopelessly disparate things; and if we wish to work with a small number of variables, we can hardly help resorting to monetary ones. And since this alliance with the aggregative approach actually runs through the whole history of Monetary Analysis, we shall henceforth restrict this term to analysis in terms of aggregates[4]—mainly, as we have seen in our study of the *tableau,*

[3] This term is due to Professor Ragnar Frisch.

[4] Some readers may welcome illustration from the leading system of Monetary Analysis of today, the Keynesian system. Readers entirely unfamiliar with the latter are requested to neglect this note. The chief variables of that system are quantity of money (sum total of cash balances demanded and supplied), national income, con-

streams of expenditure. It was pointed out there that analysis of this type does not do away with real analysis, but only confines it to the description of the behavior of individual households and individual firms. The point is, to repeat, that the social totals that result from this behavior are then dealt with as such and without referring back again, at every step, to the individual acts or decisions behind them. For instance, investment as a social total is the algebraic sum of a great many individual—positive or negative—investments. Monetary Analysis leaves the explanation of these to the Theory of Individual Households and Firms, and concerns itself only with that algebraic sum on the hypothesis *that this is all that matters for the economic process as a whole* and that all the effects on the economic process as a whole that emanate from the multitude of individual investment decisions are measured by their algebraic sum.[5] It cannot be emphasized too strongly that Monetary Analysis that accepts this hypothesis is not in as safe a position as is Monetary Analysis that does not. For it can be strictly proved that this hypothesis is in general contrary to fact. For our purpose, it is, however, sufficient to illustrate this by the example just mentioned. Suppose that, for any given year, the investment decisions of all firms sum up to zero. It stands to reason that the course of events to be expected from this will not depend solely on this fact but also on the component individual decisions: the effect will be different, for instance, if all firms have actually decided to invest nothing, that is, to leave their capital commitments unchanged, from what it would be if some of them had decided to make positive investments while others had decided to reduce their capital commitments by the same amounts. Moreover, effects—on the economic process as a whole—will differ according to the 'real' nature of the investments of the individual concerns and, in particular, according to whether these investments are complementary to, or competitive with, each other. It is

---

sumption, and investment, all measured either in money or in wage-units (the money wage of an ideal unit of labor). To these monetary aggregates correspond equal aggregative 'schedules' that embody assumptions about the behavior of households and firms in the aggregate: the schedule of marginal propensity to consume, the schedule of liquidity preference, and the schedule of marginal efficiency of capital (see below, Part v, ch. 5). Individual prices do not enter explicitly, apart from the rate of interest. It will be observed, however, that, though rate of interest is not an aggregative quantity, it fits well into a system of aggregative quantities because, unlike any other individual price, it can be readily put into a meaningful relation to them: a relation between the price of wheat and total investment does not, in general, make sense; but the relation between the interest rate and sum total of net investment does. *We must hence extend our idea of aggregative variables so as to cover any nonaggregative ones that may have to be introduced into an aggregative system.* The wage rate is the most important other instance.

[5] This point of view has been formulated by Joan Robinson, with unsurpassable energy and brilliance, in 'The Theory of Money and the Analysis of Output,' *Review of Economic Studies*, October 1933. From the standpoint defined in the text, the 'theory of money'—what we call Monetary Analysis—in fact becomes identical with the theory of social aggregates and, ultimately, of total output in terms of the monetary values of consumption and investment.

true that, so far as the immediate effects of firms' expenditure as such are concerned, our algebraic sum still tells us something. This is precisely why Monetary Analysis is not valueless. But it is not more than a part of the theory of the economic process as a whole and becomes seriously misleading if applied alone.[6]

[(b) *Monetary Analysis and Views on Spending and Saving.*] In the fourth place, as we have also seen in the case of Quesnay, Monetary Analysis is associated, not by logical necessity but nevertheless closely, with a characteristic set of views about Spending and Saving and, in connection with these, about monetary and fiscal policy. In fact, so soon as we see the economic process—primarily or exclusively—as a system of streams of expenditures, we shall be tempted to expect all sorts of disturbances from any obstruction to the even flow of these streams and, vice versa, to attribute any disturbance we observe in the economic process to such obstructions—as at least its proximate cause. The way in which households and firms handle their money and react to monetary magnitudes will thus acquire importance independently of the commodity aspect of their actions. In particular, we may be led to attach more importance to people's 'making full use of the income they receive from firms,' that is, to their spending it promptly on products of these firms than to the commodities they acquire in so doing and the prices at which they acquire them. By the same token, we may be led to identify Saving with obstruction to that flow of expenditure and, in the limiting case, to see it in the role of economic Disturber General. Thus, Monetary Analysis not only qualifies well as a tool for economists who are 'spenders' and 'anti-savers' independently of any theory but also tends to produce in the minds of its votaries the 'spending' and 'anti-saving' attitude by focusing attention on the process of the generation of monetary income behind which everything else disappears from sight.

Having cleared the ground, we must now follow the fortunes of Real and

---

[6] In partial recognition of this, modern votaries of Monetary Analysis, and in particular its leading exponent, Lord Keynes, frequently introduce a most significant restriction: they assume the organization and technique of production *and* the capital equipment as given (in the short run), thus reducing the problem before them to the question what determines (in the short run) the degree of utilization of a given industrial apparatus; and, in further simplification, they identify this greater or smaller degree of utilization with greater or smaller employment of labor so that increase or decrease of industrial investment simply means a greater or smaller wage bill. It is easy to see that, in this special case, plus and minus investments are much more nearly compensatory in their effects than they are in the general case and that hence their algebraic sum comes much nearer to expressing adequately this total effect on the economic process. But the reader should observe (a) that the restrictive assumption in question excludes the very essence of capitalist reality, all the phenomena and problems of which—including the short-run phenomena and problems—hinge upon the incessant creation of new and novel capital equipment, and (b) that, because of this, a model framed upon this restrictive assumption has next to no application to questions of practical diagnosis, prognosis, and, above all, economic policy unless reinforced by extraneous considerations.

Monetary Analysis during the epoch under consideration. Let us face at once the chief difficulty of this task. It arises from the circumstance that we meet the ideas underlying, or associated with, Monetary Analysis, as it were, on two levels—on a prescientific and on a scientific one. Ever since wages began to be paid in money, every servant girl has felt that all would be well if only her employers spent their money freely enough; and ever since trading began to mean taking in money, every trader has felt that he would be able to sell whatever it was he wished to sell, if only there were money enough or if the people who had it could only be persuaded to part with it. With exceptions that prove the rule—in nineteenth-century Europe they almost ousted the rule—this is and always has been a major item of the economics of the man in the street who never really believed in the gospel of thrift even when he paid lip service to it. The first thing that analytic effort does is to dispel some of these 'monetary illusions.' But other analytic efforts keep on creating and re-creating a Monetary Analysis on a scientific level which is sometimes just as successful in its attacks upon Real Analysis as the latter has been in its attacks upon those 'popular prejudices.' These two levels, however, are not unconnected, and this is where the historian's trouble comes in. On the one hand, popular sentiments about money and spending proved invincible. They always survived and always manifested themselves in a literary current that ran sometimes outside and sometimes inside of 'recognized' economics. And they always lent powerful support to attempts to establish Monetary Analysis on the scientific level: just as the popular success of socialist arguments forged by trained economists is not due to their scientific merits but to the fact that they fall in with cravings of the human heart that defy rational formulation, so the popular successes of scientific Monetary Analysis cannot be explained without taking into account the fact that its arguments fall in with extra-rational sentiments and therefore are likely, particularly in times of stress, to be greeted with many a sigh of relief.[7]

The most effective propositions of scientific Monetary Analysis are, in fact, those in which the public is able to discover a pointer toward the easy way out of difficulties and which bear a family likeness to what growling professionals call popular errors. On the other hand, these popular prejudices, like others, contain elements of scientifically provable truth so that association with them does not constitute a *prima facie* case for rejecting scientific Monetary Analysis. However, the exponents of Real Analysis thought that it did: not only did they neglect those elements of truth, to the disadvantage of their own teaching, but they also used the opportunity in order to represent the results of Monetary Analysis simply as new versions of what indubitably were popular fallacies. Later on, whenever they were in a position to do so, the votaries of Monetary Analysis retaliated in kind, the more zealously so because, in part, they actually did serve up exploded error in new dressing. No indictment of subjective honesty is intended. Such mix-ups will, however, arise as long as economists continue to analyze with an eye on practical programs they wish to recommend or to combat, as most of them did and do. For any effort of this kind will inevitably partake of the characteristics of political warfare in which the most primitive tactical wisdom precludes any admission to the effect that there may be something in the opponent's standpoint—with the result, in the case in hand, that both 'real' and 'monetary' analysts invariably overbid their hands. But in order to complete the analogy, it is necessary to add that they also committed all sorts of mistakes in playing them. However, we shall now try, so far as seems possible, to straighten out the tangle, first, by visualizing some broad contours of doctrinal development and, second, by mentioning a few representative names.

---

[7] The case of the United States illustrates all this to perfection.

The history of economic analysis *begins* with Real Analysis in possession of the field. Aristotle and the scholastic doctors all adhered to it. This is perfectly understandable, since there was nothing to face them except the preanalytic sentiments of the public. But, as we know, there is an important qualification to be made: they offered monetary explanations for the phenomenon of interest. *Very roughly*, this state of things prevailed until the beginning of the seventeenth century. Again, the history of economic analysis in the period under survey *ends* with a victory of Real Analysis that was so complete as to put Monetary Analysis practically out of court for well over a century, though one or two efforts were made on its behalf in the court of scientific economics, and though it continued to lead a lingering life outside of that court, in an 'underworld' of its own.[8] This victory is also understandable. It was, of course, greatly facilitated by vivid memories of monetary troubles—medieval and more recent ones—of spectacular mismanagement of banking methods—John Law's doings (see below, sec. 5) were still in everybody's mind—and by the antagonism to 'mercantilist' teachings. But powerful though they were, these factors[9] should not be overemphasized to the point of making us forget that Real Analysis was also the result of analytic advance and instrumental in bringing about further advance.

---

[8] The men who stand out from the conquering host are Turgot and A. Smith, who were to find, in the subsequent period, the ally who completed the conquest, J. B. Say. Lord Keynes (from whom I have borrowed the word 'underworld' that expresses so well the status of Monetary Analysis during the nineteenth century) dates the victory of Real Analysis from the controversy between Ricardo and Malthus (*General Theory*, p. 32). This is not correct, but there is truth in his statement that the views on policy associated with Real Analysis 'conquered England [and the rest of the world, J. A. S.] as completely as the Holy Inquisition conquered Spain.' In fact, anything savoring of Monetary Analysis ideas was disapproved of, not only as erroneous but also as not quite all right morally: it was—and, needless to say, not always without reason—associated with advocacy of dilettantic and frivolous policies and, especially in the United States, with sponsorship of loose banking practice and the silver interest.

[9] They are good examples of ideological influence if we define ideologies in a sense that is both broader and more useful than the Marxist one. Any obsession that limits our range of vision and enslaves our thought then comes within that concept. And the idea, e.g. that nothing that writers tinged with 'mercantilism' had ever written *could* be true and that anything that we should call inflationism *must* be fought at any price, may well be called an obsession.

[(c) ***Interlude of Monetary Analysis*** **(1600-1760):** ***Becher, Boisguillebert, and Quesnay.***] But between, say, 1600 and 1760, there was an important interlude of Monetary Analysis. The businessmen, civil servants, and politicians, who then took up their pens, attended to the monetary aspects of their troubles as a matter of course. They would as soon have doubted that they got wet when it rained as that more money spelled more profit and more employment, or that high prices were a boon, or that high interest was just a nuisance. But though this literature unmistakably took off from the preanalytic level of Monetary Analysis and never quite lost contact with the servant girl's economics, it did not stay there but eventually produced, barring technique, practically everything that has come to the fore again during the thirties of this century. Deferring consideration of the specifically 'mercantilist' tenets and, for the moment, also of all other matters, we shall now notice the emergence of Monetary Analysis in its most significant sense, that is, in the sense of a theory of the economic process in terms of expenditure flows. Though Quesnay's example suffices to show that, in strict logic, it has nothing to do with protectionism, the first document that presents such a theory with a clearness that is beyond the possibility of doubt was a strongly 'mercantilist' tract, Becher's *Politische Discurs* (1668).[10] This tract contains the rudiments of an analytic schema that turns upon people's expenditure on consumption—the prime mover or, as Becher said, the 'soul' of economic life. In itself the observation that one man's expenditure is another man's income—or that consumers' expenditure generates income—is as old as it is trivial. But it can be turned into a principle of analysis—the principle that Quesnay, a century later, was to embody in his *tableau*—just as can the old and trivial observation that a body at rest remains at rest unless some external force acts on it. We shall call it Becher's Principle, because he seems to have been the first to realize its theoretical possibilities. He did little to develop any *system* of Monetary Analysis and, of course, left plenty for Lord Keynes to do.[11] But so far as recommendations may be trusted at all to reveal an author's analytic schema, there is practically complete concordance between the two (excepting their views on population),[12] among other things, in the matter of domestic investment.

---

[10] *Politischer Discurs von den eigentlichen Ursachen dess Auff- und Abnehmens der Städt, Länder, und Republicken, in specie, wie ein Land folckreich und nahrhafft zu machen und in eine rechte Societatem civilem zu bringen* (i.e. how to make a country rich and populous and to develop it into a real society). Johann Joachim Becher (1635-82) was something of an adventurer. Professionally a physician and a chemist, he came to Vienna brimming over with plans and projects, and there played a certain role until he had to flee from his creditors. But his vigor and originality were universally recognized even by men like Leibniz and Stahl.

[11] Lord Keynes (*General Theory*, ch. 23) is not only generous but overgenerous in his recognition of the 'mercantilist' contribution. While this is admirable from a moral or aesthetic standpoint and appropriate in a man who cares more for the cause he espouses than for his own claims to originality, it is apt to convey a somewhat misleading picture and to obscure the amount of preanalytic wisdom and error that went into those works. Becher he does not mention. Instead he mentions W. von Schröder (1640-88; main work: *Fürstliche Schatz- und Rentkammer*, 1686), a less important, especially less original, contemporary of Becher, who seems to have been influenced both by the latter and by Thomas Mun.

It is not surprising that Becher found successors in Germany. The German Consultant Administrators were far indeed from understanding the analytic importance of his principle. But Monetary Analysis, in the sense defined, works with concepts which, though actually very abstract and indeed unrealistic, carry a surface meaning that is perfectly familiar to everyone. This surface meaning they absorbed readily because it fitted in excellently with the rest of their thought—so much so that it is not even necessary to assume dependence. Many of their diagnoses and recommendations may in fact be co-ordinated and rationalized with reference to Becher's Principle. Thus, many of them believed in the pivotal importance of high-level mass consumption or, to put the same thing into their normative way of expressing themselves, in measures that would stimulate mass consumption. For some of them, Justi for example, this was the main reason for putting so much emphasis on increase in population—as a means of expanding demand—rather than the other way round. Becher himself perceived the interaction of the two. His principle was of course relevant, as it is today, to the appraisal of the effects of high prices, saving, and luxury.

In England, neither Becher's Principle nor anything closely related to it was, so far as I know, explicitly formulated. All the more often was it implied. For instance, Potter's argument (1650) to the effect that an increase in the supply of money will increase the rate of spending and production proportionately points in this direction, and so does the analogous though more guarded argument of Law (1705).[13] The French literature offers, among others, the most noteworthy example of all—Boisguillebert's (*Dissertation sur la nature des richesses*, see ch. 4 above), which is the more interesting because, like Quesnay, he was in principle a free trader and laissez-faire advocate. He did not invoke state management to secure the steady flow of monetary values (expenditures), but on the contrary pointed to the state-made impediments to it: the export duties, the internal barriers to trade, regulative interference with agriculture and manufactures, the vicious operations of the most important direct tax, the *taille*—all of which desolated the countryside and impoverished the towns

---

[12] Becher's posthumous fame has been fostered by the eulogies of many German historians. Following the lead of Roscher (*Geschichte der Nationalökonomik in Deutschland*, 1874, p. 270), they have kept on listing a number of more or less interesting points in Becher's teaching, for instance, his concept of three market configurations of which he strongly disapproved, *monopolium*, *propolium* (forestalling), and *polypolium* (perfect competition). But there is not much in this. His lack of enthusiasm for perfect competition and his almost Keynesian dislike of laissez-faire will no doubt be judged more favorably now than it was in the nineteenth century, but it is likely that his analytic grasp was below rather than above the free-competition argument of a later time.

[13] On Potter and Law, see below, sec. 2 and 5.

because they restricted consumers' expenditure. Also, while we look upon the wage earners as the most dependable spenders, Boisguillebert, in the social pattern of his time, assigned this role to the landowners. But these differences serve only to emphasize the fundamental similarity both of his theory and his outlook upon practical problems with those of our own time. Consumers' expenditure was the active principle of economic life. Equilibrium was an equilibrium of reciprocal demand, in terms of money, of all groups for the products or services of all other groups; it would realize itself if and only if every seller promptly became a buyer.[14] Anything that interfered with prompt expenditure on consumers' goods would induce a fall in prices, hence a fall in incomes, then in turn another fall in consumers' expenditure, and thus result in cumulative deflation. Therefore his horror, never surpassed by anyone's outside the United States Senate, of that worst of all disasters—cheap bread. With delightful naïveté he warned lawyers, physicians, actors, and so forth not to clamor for low prices of agricultural products: in doing so they were 'digging their own graves'; for the landowners, who are nothing but intermediate spenders, would then find their incomes reduced and have to reduce their expenditure, and where would those lawyers, et cetera, be? Thus, his idea of a prosperous society did not involve Cheapness and Plenty but Dearness and Plenty. He did not use the phrase Fallacy of Cheapness of which modern 'spenders' are so fond, but it is evident that he meant exactly the same thing. Since this question has never ceased to arouse interest—at least in that no-man's land that lies between professional and popular economics—we had better take this opportunity to comment upon it.

[(d) *Dearness and Plenty versus Cheapness and Plenty.*] First of all, it is quite clear that both of the opinions envisaged are strongly rooted in the public mind and that the politicians, legislators, and administrators who took action in order to give effect to the one or the other simply responded to popular demands. This is as true today as it was for the price edicts of the later Roman Emperors, and explains not only the contradictions in professed motives and in actual measures that we observe but also the many insincerities in the use of apparently general arguments for what was meant to improve the relative position of some particular group. Broadly speaking, the workman always wanted low prices of *commodities*, the businessman high prices, and both assumed uncritically the absence of any further effects of either cheapness or dearness. Early analysis, here as elsewhere, proceeded from those popular sentiments and rationalized and reshaped them into doctrines. But in doing so, writers—

---

[14] This involves the concept of aggregate demand, in terms of money, for output as a whole and may hence be said to anticipate the Malthusian (and Keynesian) concept of aggregate demand which will be discussed on a later occasion. It has been observed already that, almost a century after Boisguillebert, essentially the same idea was sponsored by G. Ortes (see above, ch. 3, sec. 4d): to say that total consumers' demand is the limiting principle of production (employment) comes to the same thing as saying that it is the active principle of production.

again: here as elsewhere—usually sided with the one or the other and hence were slow, and often unwilling, to see the elements of truth in the other. The scholastic doctors associated prosperity with cheapness; dearness they associated with famine and mass misery. The English businessmen-economists of the seventeenth century, quite naturally in the conditions of their environment, inclined to the opposite position but not always: some, for example Roger Coke, made a case for Cheapness and Plenty; but the majority associated Dearness and Plenty—and, so we may add, a low rate of interest—with brisk trade and high levels of employment. It will be seen that the difference between them, as well as the difference between their majority and the scholastic doctors, was entirely due to differences in the situations that different writers and groups of writers envisaged, so that there really was no logical incompatibility between what at first blush looks like diametrically opposed views. But nobody saw or admitted this, for everyone wanted to teach a practical lesson. And this remains true for the more refined analysis of the eighteenth century. The high-price argument proved difficult to beat and was, at least in some respects, upheld by front-rank men, such as Boisguillebert and Quesnay, but it was beaten eventually, the tenable and even suggestive parts of it no less than the really fallacious ones. A. Smith cast his vote for Cheapness and Plenty, and practically all nineteenth-century economists of standing followed him. Again, it is to be observed that all that the Cheapness-and-Plenty school really did was, first, to assert such trivial truths as that any general level of prices and monetary expressions to which the economic process is adapted is, so far as a closed economy is concerned, as good as any other and that, so far as this goes, it is only the relations between some prices and others that matter, for instance, the relation between commodity and factor prices; second, to interpret cheapness in terms of effort rather than in terms of money; third, to accept the fall in money prices that occurs in consequence of accumulation and improvement as the natural method for giving effect to the increasing cheapness of things in terms of effort; and, fourth, to make light, on the one hand, of the disturbances that are inseparable from falling prices and, on the other hand, of the possibilities of stimulation, inherent in policies of rising prices. There was really nothing in all this that can properly be called a fallacy. In important respects, the victory of the Cheapness-and-Plenty advocates spelled analytic advance. But it was a one-sided advance that neglected many promising suggestions of the Dearness-and-Plenty men.

But, second, it should be observed that the slogan of Dearness and Plenty is not necessarily connected with Monetary Analysis in the sense of analysis in terms of monetary aggregates. Evidently, there is nothing in the latter to prevent us from associating prosperous conditions with cheapness. On the face of it, then, the connection between Monetary Analysis in that sense and dearness is historical only and therefore calls for special motivation in each case. In the case of Boisguillebert, this requirement can be easily met. His high-price argument was really an argument about high prices of agricultural products, and the effects of these on welfare were motivated by the consideration that they meant high incomes for the landowners on whom Boisguillebert principally relied for doing the spending: just as modern economists identify high wage rates with a high total income of the working class and this with liberal expenditure by consumers, so Boisguillebert identified high prices of agricultural products with high rents, high rents with liberal expenditure, liberal expenditure with high levels of employment and welfare. Here, then, we have a logical relation between Monetary Analysis and a high-price philosophy. But Verri's argument to the effect that an increase in the supply of money, owing to its stimulating effects on production, may induce a fall in prices (Verri is the most important pre-Smithian authority on Cheapness and Plenty) could be worked up into a piece of Monetary Analysis that would be allied to a low-price philosophy.

Quesnay was of the same opinion in regards to prices (see, especially, his *Maximes générales*, 1758). He also thought that, whereas plenty and low value are not riches, and scarcity and dearness spell misery, abundance and dearness spell opulence: prices must not be allowed to fall because *telle est la valeur vénale, tel est le revenu* (XVIII). One must not think that cheapness is advantageous for the poor—it only makes their wages fall. And the means (*aisance*) of the lowest classes must not be diminished (XIX), for then their consumption (that is, total demand in terms of money or spending) will be reduced, and this in turn will reduce production and income. But nothing is so characteristic of this type of theory, which can be so easily translated into modern language of familiar ring, as is the attitude to saving, adumbrated by Boisguillebert, fully developed by Quesnay. In this analytic schema the prompt onward flow of purchasing power is everything. Saving is believed to interrupt it. Hence saving is a sort of public enemy. Quesnay makes it one of his *maximes: que la totalité des sommes du revenu rentre dans la circulation annuelle et la parcoure dans toute son étendue* (VII). There must be no formation of *fortunes pécuniaires* (accumulations of actual cash?). Landowners and those who practice lucrative professions must not retain 'le pécule du royaume au préjudice de la rentrée des avances de la culture . . . : cette interception du pécule diminuerait la reproduction des revenus et de l'impôt.' *Le pécule* may no doubt be interpreted in the sense of uninvested savings. Even so, the similarity with Keynesian views is striking: in itself, saving is sterile and a disturber; it must always be 'offset,' and this offsetting is a distinct act that may or may not succeed. A fairly strong anti-saving tradition thus acquired additional support shortly before it almost vanished into thin air. This is all that need be said about the monetary theory of the physiocrats.

How was it then that Real Analysis conquered so easily and completely? This question will be answered in the last two sections of this chapter, where two of the chief battlefields of its victorious campaign will be surveyed, the theory of saving and the theory of interest. A general answer may, however, be given at once: the reason for the defeat or rather the collapse of Monetary Analysis in the last decades of the eighteenth century was its weakness. Even if, for the sake of argument, we grant without qualification that the principle of monetary analysis is sound and that the modern development of it is an improvement upon the real analysis of the nineteenth century, it should be clear that the latter was not less superior to the monetary analysis of the eighteenth. Such spirals of advance are, I believe, not uncommon: theories that it is an achievement to displace may return to displace those by which they had been displaced, and both the displacement and the return may benefit that strange thing, scientific knowledge.

2. FUNDAMENTALS [1]

We now turn to the theory of money in the narrower and still more usual sense—let us say, briefly though imperfectly, the theory of money as a technical device. For this purpose, it is convenient to introduce a few terms that will facilitate exposition throughout the rest of this book.

[(a) *Metallism and Cartalism: Theoretical and Practical.*] By Theoretical Metallism we denote the *theory* that it is logically essential for money to consist of, or to be 'covered' by, some commodity so that the logical source of the exchange value or purchasing power of money is the exchange value or purchasing power of that commodity, considered independently of its monetary role. It is true that in principle any commodity can be chosen to serve as money. But the term Commodity Theory of money has also another meaning. This is why, availing ourselves of the fact that in modern times only gold and silver have been normally chosen for that role, we prefer the term Metallism, though it is not strictly correct. It is also true that the 'standard' chosen may consist of more than one commodity: the singular is used merely in order to avoid adding 'or commodities' each time. By Practical Metallism we shall denote sponsorship of a principle of monetary policy, namely, the principle that the monetary unit 'should' be kept firmly linked to, and freely interchangeable with, a given quantity of some commodity. Theoretical and Practical Cartalism may best be defined by the corresponding negatives. Thus, we shall speak of theoretical cartalism wherever we find denial of the proposition that it is logically essential for money to consist of, say, gold, or to be promptly convertible into gold; of practical cartalism wherever we find sponsorship of the principle of policy that the value of the monetary unit 'should' not be tied to the value of any particular commodity.[2]

---

[1] [J. A. S. had tentatively suggested 'Ground Theory' (*Grundlagenforschung*) as the title of this section, but he used 'Fundamentals' as the title of the corresponding sections in Part III (ch. 7, sec. 2) and Part IV (ch. 8, sec. 3).]

[2] The words Metallism and Cartalism are borrowed from G. F. Knapp's *State Theory of Money* (see below, Part IV, ch. 8, sec. 3). Since, according to the metallist view, the theory of money derives directly from the logically prior theory of barter, metallist theories are (roughly or exactly, I am not quite sure) what L. von Mises has called

These distinctions owe their importance for us to the fact that theoretical and practical metallism need not go together. An economist may, for instance, be fully convinced that theoretical metallism is untenable, and yet be a strong practical metallist. Lack of confidence in the authorities or politicians, whose freedom of action is greatly increased by currency systems that do not provide for prompt and unquestioning redemption in gold of all means of payment that do not consist of gold, is quite sufficient to motivate practical metallism in a theoretical cartalist; this does not involve any contradiction. But the reader will realize that this fact may cause great difficulties in interpreting authors who are in the habit of confusing theoretical and practical considerations. Nor is this the only reason why it is not always easy to tell whether or not a man should be classed as a theoretical metallist. For, without being one, he may still believe that 'the most salable commodity' constitutes the historical as distinguished from the logical source of the phenomenon of money.[3] Again, he may wish to stress the role of government in choosing the commodity that is to serve as money and its power to alter this decision in various ways. In doing so he may easily, if not very sophisticated or careful, use language that will tempt us to class him as a cartalist. We remember that this difficulty arose in the case of Aristotle (ch. 1, above). Finally, basic theories are malleable and writers are often inconsistent, still more often vague. When we find that a writer compares money to a ticket—a ticket that admits the bearer to the great social store of all goods—we feel inclined to register him as a cartalist. But the phrase need not mean much, and both J. S. Mill, who used it in the nineteenth century, and Berkeley, who used it in the eighteenth, are more properly called metallists. There is no denying that views on money are as difficult to describe as are shifting clouds.[4]

[(b) *Theoretical Metallism in the Seventeenth and Eighteenth Centuries.*] Theoretical metallism, usually though not always associated with practical metallism,[5] held its own throughout the seventeenth and eighteenth centuries

---

catallactic theories of money (καταλλάττειν, to exchange). But the word Metallism conveys the essential point more tellingly, besides offering easy transition to Monometallism and so on.

[3] Here we brush against a highly interesting question of methodology. [J. A. S. wrote: please leave rest of page for note.]

[4] [The next few pages were inserted by J. A. S. from an earlier version typed in March 1944 (see Appendix).]

[5] I am taking it for granted that theoretical metallism is untenable, i.e. that it is not true that, as a matter of pure logic, money essentially consists in, or must be backed by, a commodity or several commodities whose exchange value as commodities are the logical basis of their value as money. The error involved consists in a confusion between the historical origin of money—which, in very many cases, although perhaps not universally, may indeed be found in the fact that some commodities, being particularly salable, come to be used as the medium of exchange—and its nature or logic—which is entirely independent of the commodity character of its material. This type of error occurs very frequently in all fields of social analysis, especially in its early stages: it requires considerable analytic experience to perceive that primitive forms of social institutions may be more complex than modern ones and that they

and prevailed victoriously in the 'classical situation' that emerged in the last quarter of the latter. Adam Smith substantially ratified it. And for more than a century to come it was almost universally accepted—by nobody more implicitly than by Marx—so much so, in fact, that the majority of economists came to suspect not only unsoundness of reasoning but something very like obliquity of purpose behind every expression of antimetallist views.

This development, as we know, was in accordance with established tradition. The philosophers of natural law and those Consultant Administrators who were directly influenced by them simply repeated and developed the teaching of Aristotle and the scholastic authors. But the majority of those writers on money who cannot be proved to have experienced any influence from that quarter—for instance the English merchant economists—also fell in with that tradition. Examples abound for all countries. For England it will suffice to mention, first, some economists of the first rank, such as Child, who clearly identified money with those parts of the stocks of gold and silver that fill the monetary function and held that in spite of this function gold and silver, coined or uncoined, still remained commodities exactly like 'wine, oil, tobacco, cloth and stuff'; Petty, who also reasoned about money in terms of its material; and Locke,[6] who did likewise, though he was more ready to admit

---

may hide, rather than reveal, logical essentials. We shall have to return to this before long.

But one may realize all this and yet be a practical metallist, i.e. believe that in some or all cases effective association of the monetary unit with, say, gold is the best or even the only way to establish a monetary system or to make it function. This is not a matter of pure theory, however, and may be right or wrong according to circumstances and individual or group standpoints and interests. But although theoretical and practical metallism are logically independent, the reader will not be surprised to find that they are not always easy to distinguish. Few authors are quite explicit on the subject; the majority is to this day in the habit of confusing them; but practical metallists and practical antimetallists often display a tendency to strengthen their arguments, concerning the practical expediency of associating the monetary unit with a quantity of metal, by a metallist or antimetallist theory. Two additional facts further increase the difficulties of interpretation: on the one hand, metallist and antimetallist opinions are not so strictly incompatible as one would expect but admit of a great many nuances; on the other hand, turns of phrase—such as 'money is a ticket'—that do seem to point clearly toward one of the alternatives may mean very little if not followed up. Such difficulties we have met already in the case of Aristotle. I am by no means absolutely sure that I was right to class him with the theoretical metallists. Galiani, whom we shall meet presently, interpreted him in the opposite sense. In the case of tracts written without minute attention to fundamentals, these difficulties often become the more insuperable the deeper we probe into an author's ideas. What follows in the text must be read in the light of these considerations. I prefer putting my doubts frankly before the reader to dogmatizing with a confidence I do not feel.

[6] The wide horizon of the author of the *Essay concerning Human Understanding* and his sustained interest in economic facts and problems (of which his journal gives ample proof) should make it possible to construct a comprehensive system of his economic thought. This has in fact been attempted more than once, most successfully, perhaps, by W. Roscher (*Zur Geschichte der englischen Volkswirthschaftslehre*, 1851)

that the monetary function makes a diffierence; Hume,[7] whose teaching on this particular point differs from Child's only in explicitness and polish; Cantillon (op. cit. Part I, ch. 17), whose theoretical metallism exerted considerable influence in France; and, second, the authors of what may be considered as the two standard English works on money of the seventeenth and the eighteenth centuries, Rice Vaughan[8] and Joseph Harris.[9]

---

and J. Bonar (*Philosophy and Political Economy*, 1893). Nevertheless, though we have had, and shall have again, to mention his name in other connections, his claim to a place in the history of economic analysis rests exclusively on his work on money (mainly in *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money*, 1692; the *Further Considerations* . . . 1695, add but little), which, though date and form of its publication were prompted by current controversies, yet embodies the thought of decades and amounts to much more than a tract for the day, to much more also than the title conveys, by virtue of the energy with which the author digs down to fundamental principles. Even so, however, we cannot speak of a great, still less a faultless, contribution to monetary analysis. Slips are frequent and, whatever the degree of 'subjective originality,' there is little that was not said as well or better by other writers at about the same time. The influence exerted was considerable also on the Continent.

Our right to class him as a metallist can be fully established from the structure of his argument. Doubts might be raised, however, on the strength of Locke's statement that money exists by virtue of common 'consent.' The question is the same as that which arises in connection with Aristotle's συνθήκη (see above, ch. 1), and may, I think, be answered in the same way: on the one hand, even though money evolves from the habit of using one commodity for the purposes of indirect exchange of the others—in order to facilitate barter—this might be expressed by saying that people 'agree' on the choice of that commodity; on the other hand, even though the monetary commodity acquires a 'price' through the market mechanism, this price may be said to arise from 'consent' as indeed may any other.

[7] David Hume's 'Of Money' is one of the major contributions contained in his *Political Discourses* (1752). Its position in the history of economics, while not undeserved, is due to the force and felicity with which it formulated the results of previous work rather than to any novelties. However this does not necessarily exclude 'subjective originality.' The main items will be mentioned in the text.

[8] Rice Vaughan, *A Discourse of Coin and Coinage* (about 1635, publ. 1675), reprinted in McCulloch's *Select Collection of Scarce and Valuable Tracts on Money* (1856). Perusal of this creditable performance may serve usefully as an antidote for all those who have learned to look upon seventeenth-century thought on money as unrelieved nonsense. But it may also serve as an illustration for the difficulties of interpretation alluded to in footnote 6 above. Vaughan falls in promptly with a typically metallist line of reasoning, but when explaining the nature of money, he uses phrases which taken by themselves would also admit of antimetallist interpretation.

[9] The *Essay upon Money and Coins* (two parts 1757 and 1758) by Joseph Harris (1702-64) has some claim to being considered one of the best eighteenth-century performances in the field of monetary analysis. Its importance for us does not, of course, consist in his various recommendations that account for the survival of his name (his monometallism, his views on foreign trade, which were not very far removed from those of Hume and Smith, and so on) or in his copious historical references but in what might be termed the theoretical anchorage of this theory of money and of foreign ex-

For the rest, we shall confine ourselves to instances from the Italian literature on money, which throughout the period kept a higher level than any other. Practically all the leading men were uncompromising metallists. The most important names are Scaruffi, Davanzati, Montanari, Galiani, and Carli. Beccaria and Verri should be added as examples of the treatment accorded to the subject of money in the comprehensive treatises on general economics.

Almost all the works of these authors have been republished in the Custodi collection (see above, ch. 3). In this note an attempt will be made to convey a general idea of the performance of each author excepting those of Beccaria and Verri, which are characterized elsewhere (ch. 3, sec. 4d above). Verri's and Carli's contributions, moreover, will again be met with in another connection (ch. 7, Mercantilism). Verri's monograph *Dialogo sulle monete* (1762) should not go unmentioned, however.

Gasparo Scaruffi (1515?-84), a banker of Reggio in the Emilia, published in 1582 a monograph on money entitled *Alitinonfo*, which admirably illustrates the range of sixteenth century thought—starting from the functions of money and dealing with problems of coinage in a strongly metallist vein: money is a stamped piece of metal, the stamp has only declaratory importance. His proposal of international bimetallism (somewhat marred by an irrational faith in an invariable relation of 1 : 12) with an international unit to be issued (without seignorage) by an international authority *implies* a lot of fairly advanced theory. But very little of it comes out explicitly. Thus the step is great indeed to Bernardo Davanzati (1529-1606), 'un mercante letterato Fiorentino,' as Montanari called him. Davanzati's *Lezione delle monete* (1588; see also *Notizia de'cambi*, 1582) is the 'all time high,' also as regards literary elegance, of the metallist theory of the origin and the nature of money.

About a century later, Geminiano Montanari (1633-87), a professor of mathematics and astronomy in Bologna and Padua, wrote a *Breve trattato del valore delle monete in tutti gli stati* (1680); followed by *La zecca in consulta di stato* (later title, *Della moneta*, 1683-7), which presents the same teaching in a more fully developed form but without adding anything essential to it.

The Neapolitan, Ferdinando Galiani (1728-87), a typical eighteenth-century *abbé*, sparkling with esprit, did for his time what Montanari had done for the seventeenth, and Davanzati for the sixteenth, century in his treatise *Della moneta* (1751; first book: *De'metalli*; second book: *Della natura della moneta*; third book: *Del valore della moneta*; fourth book: *Del corso della moneta*; fifth book: *Del frutto della moneta*—not only on interest, however, but also on public debts and exchange), which would have been received with respect if it had appeared in 1851. Another work of Galiani's will be mentioned in the next chapter. One point about his thought must be emphasized before we tear ourselves away from one of the ablest minds that ever became active in our field: he was the one eighteenth-century economist who always insisted on the variability of man and on the relativity, to time and place, of all policies; the one who was completely free from the paralyzing belief—that then crept over the intellectual life of Europe—in practical principles that claim universal validity; who saw that a policy that was rational in France at a given time might be quite irrational, at the same time, in Naples; who had the courage to say: 'Je ne suis pour

---

changes; he put the subject into a wide framework of general economic principles of which he never loses sight. His treatment thus contrasts favorably with that of all those authors, old and new, who fail to see that any satisfactory theory of money implies a theory of the economic process in its entirety.

rien. . . Je suis pour qu'on ne déraisonne pas' (*Dialogues sur le commerce des blés*, 1769, first dialogue); and who properly despised all types of political doctrinaires, including the physiocrats. There is quite a Galiani literature, and there are several reprints of, and selections from, his works. They are listed in Giorgio Tagliacozzo's *Economisti Napoletani dei sec. XVII e XVIII* (pp. lxv and lxvi), which also contains an essay on Galiani and extracts from *Della moneta* and the *Dialogues*.

Gian Rinaldo (Conte) Carli (1720-95), professor of astronomy at Padua, later on president of the Board of Finance in the Milanese state (then a part of the Habsburg monarchy), in which capacity he, among other things, reformed the coinage according to a plan of his own, a most versatile writer whose comments on the United States in *Delle lettere Americane* (1st ed. 1780; 2nd ed., in 4 vols., 1786) deserve mention even in a sketch like this, must be listed here because of his work entitled *Delle monete* . . . (first instalment, under the title *Dell'origine e del commercio della moneta* . . . 1751, the whole work in 3 vols., 1754-60), which includes the essay *Del valore e della proporzione dei metalli monetati con i generi* [commodities] *in Italia*, which contains the contribution to be mentioned below. Other economic writings of his will be noticed in the next chapter.

It is but natural that most of such advance as the analysis of monetary processes made links up with metallist foundations, even where, in strict logic, antimetallist starting points would have been more appropriate. This should not surprise us, however: in spite of its shortcomings, theoretical metallism, properly handled, gets us almost as far as would a more correct theory—which is precisely one of the reasons why it proved so hardy a plant.

[(c) *Survival of the Antimetallist Tradition.*] There was also, however, an antimetallist tradition, weaker no doubt but equally ancient, at least if we choose to trace it to Plato. It received impetus from governments in financial difficulties, and from inflationists, 'reflationists,' and bank promoters of the period—though the proponents of bank schemes were not all either inflationists or antimetallists,[10] and though there is no necessary relation between inflationism and theoretical antimetallism—but its survival during our period must not be wholly attributed to this factor. Of continental writers it will be enough to mention Ortes and Boisguillebert.[11] Corresponding English instances are Potter, Barbon, Berkeley, Steuart, and, if we claim for England that Scotsman who became a Frenchman, Law.

---

[10] Examples of metallist sponsors of national-bank schemes are numerous. The author of the proposal of 1576 was one. John Cary (*An Essay, on the Coyn and Credit of England*, 1696 and *An Essay towards the Settlement of a National Credit*, same year) was another. The writers who stood for the foundation of the Bank of England were all metallists so far as I know.

[11] Ortes, *Economia Nazionale* (1774). His theoretical antimetallism—money defined as a symbol of wealth and expressly excluded from the items that constitute wealth itself—is another one of the striking parallelisms with the work of Sir James Steuart. Boisguillebert was antimetallist in the sense that he did not consider gold and silver—or, so we may obviously add, any other commodity—to be the essential material of money. The question why, if that be so, money should ever have been made from a material that could serve other uses he answers correctly by pointing to the fact that money so made is a pledge or security (*gage*) for the future delivery of whatever the payee really wants to have and that such a pledge is practically necessary where the payer's credit is not beyond all doubt. To deny that the concept of money requires a

William Potter's *The Key of Wealth*, published (anonymously) 1650 and followed by two interpretative publications, recommends a plan, namely the foundation of a corporation of tradesmen (to be strengthened by another body 'insuring' the credit of these tradesmen) which was to accept—or, what in this case amounts to the same thing—to issue 'bills' secured by land, buildings, and other assets and intended to circulate like legal tender money. This plan for mobilizing physical property not only puts Potter in the position of a forerunner of the land-bank projectors (sec. 5) but also obscures the analytic work behind it, which is of considerable interest. The antimetallist character of both the plan and the analysis is beyond doubt, though Potter does not entirely sever the connection of his bill currency with gold and silver, because, if such a plan were adopted, that connection would reduce to one of historical origin only: though money would have originated in the form of a commodity, its value and behavior would no longer be governed by that commodity.

The reputation of Nicholas Barbon, a physician who embarked upon various business enterprises, suffered in his own time as well as later on, from the many freakish elements not only in his plans but also in his analytic arguments. In addition, he was one of the land-bank projectors. In spite of this, he must, I think, be ranked with, say, the top half-dozen English seventeenth-century economists. We shall also meet him in another connection, but his main importance for us is in the field of money and interest. His *Discourse of Trade* (1690) has been republished by J. H. Hollander. Reference must also be made to: *A Discourse concerning Coining the New Money Lighter* (1696).

George Berkeley's (1685-1753)—Bishop Berkeley's—contribution to economic analysis is not on a level with his contribution to philosophy. It is chiefly contained in his *Querist* (1st ed., 1735-7). The idea of putting a prolonged argument into an endless string of wearying questions may not be to everyone's taste. But the forceful common sense, which is the strong point of his philosophic thought, is conspicuous in almost every one of them.

Sir James Steuart we have met already. For the subject of money it is necessary to add other publications to his *Principles*, especially the *Principles of Money applied to the Present State of the Coin of Bengal* (1772).

John Law (1671-1729), I have always felt, is in a class by himself. Fi-

---

commodity element in order to be logically complete and then to introduce the latter on the score of (good or bad) reasons of practical convenience is the very definition of theoretical antimetallism, combined (if these reasons are held to be valid) with practical metallism. But the term 'pledge' is also used by writers of metallist persuasion. It occurs, e.g., in R. Vaughan's explanation of the nature of money.

nancial adventurers—but is it fair so to call that administrative genius?—often have a philosophico-economic system of sorts. The Pereires of Crédit Mobilier fame had one (of St. Simonist complexion). But Law's case is different. He worked out the economics of his projects with a brilliance and, yes, profundity, which places him in the front rank of monetary theorists of all times. And this is all that matters for us. Since it is plain, however, that his analysis has been condemned, for about two centuries, primarily on the strength of the failure of his Banque Royale, it is pertinent to point out, first, that its predecessor, the Banque Générale, founded 1716, was a perfectly orthodox bank that was to issue notes and to receive deposits payable on demand and to discount commercial paper—no antimetallism about that—and that the Banque Royale and the Compagnie des Indes, which it absorbed, failed because the colonial ventures combined in the latter did not, for the time being, prove to be the source of anything but losses. If these ventures had been successful, Law's grandiose attempt to control and to reform the economic life of a great nation from the financial angle—for this is what his plan eventually amounted to—would have looked very different to his contemporaries and to historians. Even as it was, that gigantic enterprise was not simply a swindle and it may well be doubted whether France was the worse for it, on balance. However, economists not only fell in with the popular opinion that the scheme was nothing but swindle but also pointed to certain technical defects in it that were in fact important subsidiary causes of its failure. Thus that event acquired considerable influence on the evolution of what eventually became the classic theory of banking.

Law's performance as a monetary theorist is contained in his tract: *Money and Trade considered, with a Proposal for supplying the Nation with Money* (1st ed. 1705, 2nd ed. 1720; republ. in Somers' *Tracts*, 1809; French version, together with other writings including interesting *Mémoires justificatifs*, in the Guillaumin edition of *Économistes-financiers du XVIII^{e} siècle*, under the title of *Considérations sur le numéraire et le commerce*). The reader who wishes further information about that colorful personality is referred to A. W. Wiston-Glynn, *John Law of Lauriston* (1907), and P. Harsin, *Étude critique sur la bibliographie des oeuvres de John Law* (1928).

One of his plans was concerned with a land bank that was to issue legal tender paper money up to a certain proportion of the value of land and to receive as deposits *for placement* money that would otherwise lie idle, so that money would never be either too cheap or too dear. In this he followed the English land-bank projectors who must now be mentioned briefly.

The landed gentlemen in the House of Commons were no more, than were and are any other agrarians, able to see why they should not borrow as easily and cheaply as traders or financiers, and they did not take kindly to arguments about the difference between a bill and a mortgage. A land bank that, among other things, might satisfy these longings eventually became a Tory plank when the foundation of the Bank of England was in the offing. At the right time (1693) an intellectual, Hugh Chamberlen, an obstetrician by profession, presented a plan of a land bank where landowners would get loans at 4 per cent and the government would get more money than it had got from the Bank of England. The plan, which failed through lack of financial support, need not detain us. But there were supporters who attempted to supply it with an analytic background. Barbon, as we already know, was one. John Asgill (*Several Assertions Proved* . . . 1696, republ. in the Hollander series) was another; his tract illustrates the truth, which I try incessantly to emphasize, that the fact that *we* may be able to see some point in that scheme does not in itself salvage every devious argument that may have been put up for it. But John Briscoe (*Discourse on the Late Funds* . . . 1694; abstract of it in the same year), who claimed to have been plagiarized by Barbon and Asgill and was himself accused of having plagiarized Chamberlen, did provide some analytic groundwork with respect to which all those accusations are meaningless. Many economists would call him a metallist because he attributes importance to a stock of gold and silver. On reflection it will be realized, however, that a man's belief in the usefulness of a stock of universally acceptable commodities proves nothing about his views concerning the nature of money.

We cannot, and need not, go into the literature pro and con the foundation of the Bank of England. Not uninteresting in other respects, it was, so far as I know, sterile in the one that interests us here.

Barbon was more definite than anyone else in renouncing theoretical metallism on the ground that 'money is a value made by law,' to which the value of its material is not essential. John Law implies rather than states the same thing when emphasizing the virtues of paper money, which consist in its quantity's being amenable to rational management. Berkeley is, as far as I know, the author of the ticket analogy: 'Whether the true Idea of Money, as such, be not altogether that of a Ticket or Counter?' (*Querist*, no. 23). The only effort at building a theory of money on an antimetallist basis stands to the credit of Sir James Steuart. But he made so little headway and slipped up so often that the promising beginning was lost in the metallist current.

The point is this. The practice of the epoch, especially the practice of the four great clearing and deposit banks,[12] had familiarized economists with the idea of a money of account which was defined by quantities of metal and which existed only as a bookkeeping device for the purpose of facilitating large-scale trade and finance in a world of numberless and ever-changing currency systems. In this sense the money of account also entered monetary theory of the metallist type. Galiani called it *moneta ideale* or *moneta immaginaria*,[13] and distinguishes it from *moneta reale*, which consists of actual *pezzi di metallo*. Steuart (*Principles*, Book III) makes the same distinction between 'money of accompt' and 'money-coin,' but with him this distinction acquired a different meaning. Having previously (*Principles*, Book I, p. 32 of the edition of 1767) *defined* money as 'any commodity which purely in itself is of no material use to man but which acquires such an estimation from his opinion of it as to become the universal measure of what is called value . . .'—a faulty way of defining a pure *numéraire* of which he thus may be called the discoverer[14]—he then starts from a money of account, considered as an 'arbitrary scale' for measuring values and, unlike the money of account of practice and also of metallist theory, devoid of any commodity connotation. He tries unsuccessfully to find primitive instances of such a unit,[15] and does not succeed in explaining how such a unit can be theoretically constructed and how it might function in practice. But he had the idea and he also saw metallic money in its true light, namely, in the light of a very special case.

---

[12] Of Amsterdam, Hamburg, Genoa, and Venice.

[13] If there be any difference between these two phrases, it has escaped me.

Every writer who went into fundamentals at all recounted and developed, as the scholastics had done, the particular virtues that explain why the precious metals proved so universally acceptable as to acquire their monetary role (their divisibility, mobility, and so on). Somewhat less trivial was the listing of the four functions of money that were to gain such prominence in the nineteenth-century textbook: the Aristotelian 'measure of (exchange) value' and 'medium of exchange' were supplemented by 'store of value'—an element much emphasized by the specifically mercantilist writers (see next chapter)—and by 'standard of deferred payments,' though I know of no case where these four functions appear neatly side by side—some writers even stressed the first only and others the second only. It was gradually realized that these two functions are separable and that their theories are different.

The economists of that period had before their eyes, as had the scholastics, almost all the forms of bimetallism that it is possible to conceive and hence all the practical problems that are incident to this system. It is the more surprising that so little progress was made with its analysis. In particular, the essential point about the legal ratio of the two metals does not seem to have been noticed: theorists realized, of course, that the metal which this ratio overvalues with respect to the other will tend to drive out the one it undervalues; they had discussed this phenomenon at least from Molina's time—one may in fact, if one so desires, subsume it under Gresham's law; but they failed to see that, so long as both metals are in circulation, this mechanism will tend to increase the market value of the one and to decrease the market value of the other and thus tend, within limits, to stabilize the market values of both, which is the most interesting property of bimetallism. Locke, who was monometallist on principle, even argued on general grounds that there should be no legal ratio at all—no more than a legal rate of interest or a legal exchange rate—without observing that in this case the system becomes indeterminate.[16] Beccaria and others are not more satisfactory on this matter.

---

[14] It will be observed that the use of the word commodity does not make him a metallist. For a commodity that, by definition, is incapable of serving any purpose outside of its monetary function is not a commodity in the relevant sense of metallist theory.

[15] He mentions the *macute*, a unit that is supposed to have been current among West African tribes. Perhaps this was suggested to him by Montesquieu (*Esprit des lois*, Book XXII, ch. VIII), who was also an antimetallist and used the *macute* as an instance of a monetary unit that was a *signe* [of value] *purement idéal*. But the instance is of doubtful validity.

It will be convenient, before going on, to touch briefly upon a number of topics, some of them of great importance in themselves, that cannot be dealt with fully in a history of economic analysis.

First, questions of coinage were bound to be eagerly discussed under circumstances in which the state of the currency continued to give trouble. The large literature on technique, principally Italian, contains little that is of interest to us. But we may mention the question of seignorage. The old feudal privilege of kings and princes to coin money and to levy a tax in doing so, often in addition to a fee (brassage as it was sometimes called), was onerous even when it did not lead to frequent recoinage and produced an irresistible popular demand for free coinage. Accordingly, in England seignorage was abolished in 1666, while in other countries the tendency was to reduce it to the cost of coinage. There are two points about this that are relevant to the theory of money. One is that some writers, among them Sir William Petty, maintained that free coinage was essential for gold and silver to fill the function of money: if any charge at all were made for coining, they would no longer be true measures of the value of other things—which looks like a theoretical slip. The other is that the act which introduced free coinage was motivated by a desire to attract gold and silver—the costs to be defrayed by import duties on other commodities—and therefore was a typically 'mercantilist' measure. Economists were by no means in love with it and practically the entire free-trade chorus from North to Smith and from Smith to Mill recommended a cost-covering charge as did most continentals, though in the case of the German economists we might be tempted to attribute this to the fact that they were advising poor governments.

This naturally leads, secondly, to the discussion of devaluation or debasement ('raising the coin'). The old arguments, characteristic of strict metallism, that to debase was to defraud continued to be repeated: we find them in a host of writers, including Locke, Justi, and A. Smith.[17] But economists came increasingly to take another and much more interesting view of the matter: they began to attend less to rights and wrongs and more to the effects of debasement upon the economic process. Sporadically, we find considerations of this type even in the sixteenth century, when people discussed whether debasement was advantageous or disadvantageous for the public finances. In the second half of the seventeenth and in the eighteenth century, discussion turned to the effects on the foreign trade and on the economic development of a country. Let us take cursory notice of a few beacon lights on this route. First, the English currency (silver monometallism with an increasing actual circulation of gold), having fallen into bad repair in the last decades of the seventeenth century, William III's Whig government, in which Charles Montague managed financial affairs, carried a bill (1698) according to which the silver coins were to be restored to their old weight and fineness at the public expense, this expense to be covered by a window tax, an operation that was completed by 1699. The debate on the measure is glorified by the name of Locke, who was the literary protagonist on the side of the government, and its interest to us reduces to the light his contribution sheds on the extent of his comprehension of monetary phenomena. Unfortunately, it is a sorry picture that unfolds itself before the eyes of Locke's reader. It is not only that he mainly worked the fraud line—this is a moral judgment and is his affair, not ours—but he failed to see (a) that recoinage at an average of the actual silver content of the silver coins could not be called debasement or could be called so only with the qualification that the economic situation was already adapted to it, so that in effect he was advocating overvaluation of the coin and undervaluation of the silver contained in it; (b) that in consequence, unless all prices adapted themselves promptly—which was not to be expected and would have, if it had happened, greatly accentuated the prevailing depressive conditions—silver would emigrate, as in fact it did; (c) that the presence of gold coins in actual circulation was at all relevant to the problem. He even went so far as to hold that what he called debasement was futile—in fact impossible—on the ground that an ounce of silver could never be worth more than an ounce of silver! His case and his defense of it was below that of his chief opponent, Lowndes—this is what happens to the man 'who gives up to party what was meant for mankind.' It is curious and melancholy to note that both the measure and Locke's advocacy of it have been eulogized, sometimes in extravagant terms, for more than two centuries.

---

[16] I know of no clear recognition of this fact until Walras pointed it out, but Galiani recognized it implicitly. For he argued for the legal—though variable—ratio on practical grounds, one of which looks very much like it. A similar claim may be made for Massie.

[17] If economists were more given to clear statement than they are, the question what this fraud precisely consists in might well serve as a test for the presence or absence of metallist belief. If the fraud be held to consist in depriving the creditor of part of the metal that is due to him, we behold a metallist. If the fraud be held to materialize only, if, as, and when debasement or devaluation increases the money in circulation and hence decreases the creditor's potential share in the things that may be bought for money, then we behold a cartalist. The logical justification for this distinction is too obvious to require comment, but it may be well to point out that there is also a prac-

Next we shall note, from the French discussion of the monetary troubles during and after the last wars of Louis XIV, the duel between Melon and Dutot [text breaks off at this point].

---

tical difference: devaluating governments need not and often do not inject the corresponding amount of money into circulation. They may hold it—wholly or in part—or use it for payments to foreign creditors, and there are other reasons why this access of money need not act upon prices. It even may be used in ways that benefit creditors. In fact, modern experience clearly shows that devaluation and depreciation are different things, and they are universally distinguished by now.

3. DIGRESSION ON VALUE

Work in this field also proceeded from the scholastic background. We know that the scholastic doctors had developed the essentials of a realistic analysis of value, cost, and price—including a rudimentary concept of equilibrium—that needed only to be elaborated in content and perfected in technique. To some extent this is exactly what was done during the period under discussion. This work was powerfully propelled by the preoccupation with the problem of the value (purchasing power) of money. The metallist theory, as a theory of money, may not be much good in itself. But it certainly leads the economist who accepts it to inquire more closely into the problem of value in general. We shall therefore not be surprised that a great part of the best work in this field was done by students mainly interested in monetary phenomena. This is why this section stands where it does. We are going to try to bring out, by means of a brief survey of outstanding performances, the points that are most important for subsequent developments.

[(a) *The Paradox of Value: Galiani.*] The Italians from Davanzati on (*Lezione delle moneta*, 1588) were the first to realize explicitly how the Paradox of Value—the paradox that many very 'useful' commodities such as water have a low exchange value or none at all whereas much less 'useful' ones such as diamonds have a high one—can be solved and that it does not bar the way toward a theory of exchange value based upon value in use. The astounding fact that both Smith and Ricardo thought it did is, however, seen in its full significance only if we add that, for the century and a half after Davanzati, a lengthy list of writers might be compiled who understood quite well precisely how the element of utility enters into the process of pricing and that there were several Englishmen among them. John Law, in particular, in the tract quoted above (*Money and Trade considered* . . . 1705), gave a short but excellent account of the matter—actually using the examples of water and diamonds. However, we shall confine ourselves to the economist who carried this analysis to its eighteenth-century peak, Galiani.[1] Unlike Law, he was so uncompromising a metallist that he felt compelled to inquire into the value of gold and silver considered as commodities and therefore into the value of all commodities. In doing so he displayed sure-footed mastery of analytic procedure and, in particular, neatness in his carefully defined conceptual constructions to a degree that would have rendered superfluous all the nineteenth-century squabbles—and misunderstandings—on the subject of value had the parties to these squabbles first studied his text,[2] *Della moneta,* 1751 (outlined in the preceding section of this chapter).

---

[1] This, of course, involves injustice to his predecessors, to whom, in fact, he was unbelievably unfair himself. For instance, in developing Davanzati's argument, he writes in a vein of quite unwarranted superiority. Moreover, it must not be forgotten that the theory he developed was really that of the scholastics. It was not only in this matter that Galiani—like other economists—failed to acknowledge indebtedness properly. In his sociology—or, if readers prefer, social philosophy—he leaned heavily on Vico without acknowledging this debt either. See Tagliacozzo, op. cit. pp. xv (the most beautiful page in the whole Vico literature, so far as I know it) et seq., and F. Nicolini ('Giambattista Vico e Ferdinando Galiani,' *Giornale storico della letteratura italiana*, 1918, and the Note to his edition of Galiani's *Della Moneta*, 1915; but, being a philosopher, Nicolini is inclined to exaggerate the dependence, which amounted to little, so far as technical theory is concerned).

Having resolutely (first Book, ch. II) defined the term Value to mean a relation of subjective equivalence between a quantity of one commodity and a quantity of another—the objective equivalences on the market are treated as a special case of this, but he did not work out the transition from subjective to objective values in this sense—so that the phrase Value of a Commodity has no meaning except with reference to a given quantity of another, Galiani answers the question on what this value depends by Utility and Scarcity (*utilità e rarità*), and proceeds to develop these concepts in much the same way in which I suspect they are explained in many an elementary course today. Utility is not usefulness as understood by the observer—'useful' in the economist's sense is everything that produces pleasure (*piacere*) or procures welfare (felicità). Fashion, prestige value, and altruistic components are all trotted out in due course. And scarcity is the relation between the existing quantity of a thing and the uses one has for it and explains why a golden calf is valued more highly than a natural calf. To repeat, all that was not original with Galiani. The famous 'paradox of value,' which was gravely discussed again in the nineteenth century—the fact that obviously useful things fetch a low price and much less 'necessary' ones a high price—had been resolved several times before. But never before, or for more than a century to come, was this theory put forth so completely and with so full a sense of its importance. What separates Galiani from Jevons and Menger is, first, that he lacked the concept of marginal utility—though the concept of relative scarcity comes pretty near it—and, second, that he failed to apply his analysis to the problems of cost and of distribution. The first shortcoming is perhaps a reason why he stops short of a satisfactory theory of price, though he could have got further than he did in spite of it, as Isnard's later success suffices to show. Even so, however, he left his mark upon the subject. Having indicated how price derives from utility and scarcity, he ran up against the fact that this price, by limiting the quantity of the commodity consumers can procure, reacts in turn upon scarcity as felt by these consumers. It at the same time regulates, and is regulated by, demand (*consumo*). He knew perfectly how to deal with this phenomenon of interdependence. And in the three pages he devotes to the subject he actually discovered the concept of long-run equilibrium and sketched out the profit mechanism that works to bring it about, visualizing a country, hitherto Mohammedan and teetotal, that suddenly embraces Christianity and thereupon develops a demand for wine. There is a Mandeville flavor about these pages that perhaps detracts a little from what otherwise would have to be considered as a remarkable display of originality. But this does not alter the fact that but little care and patience would have been sufficient to evolve from this a much more perfect body of theory than was to be presented by A. Smith.

---

[2] There was another Italian writer on money, Giovanni Ceva (*De re nummaria, quoad fieri potuit* [!] *geometrice tractata* . . . 1711), an engineer in Mantua, who did not, so far as I can see, add anything new to the theory of money, but whom no history of economic analysis can afford to pass by because of his insight into the nature of economic theory: real phenomena are always obscure and unmanageably complex; practice is always *minus exacta*; to understand the principles of things we must hence construct rational models by means of assumptions (*petitiones*) or else we must always move in the darkest of nights (*versari in obscurissima nocte*); and the proper way of dealing with these models is by mathematics, a methodology that took two centuries to assert itself.

While Galiani thus foreshadowed much later developments (marginal utility), he also anticipated the value theory of the next hundred years (Ricardo and Marx). For, with surprising abruptness, he turns from *rarità*, by way of quantity of commodities, to labor (*fatica*) and forthwith enthrones it as the only factor of production and the only circumstance *che dà valore alla cosa*. In one sense this spoils his theory of value, but in another it is highly interesting. *Fatica* means quantity of labor—corrected for the social habits that determine how many days a year and how many hours a day a man actually works and for the differences in natural ability (*talenti*) which account for the different prices of the *fatica* of different people—and, with a qualification for the monopoly price of unique things (*Venere de' Medici*, for instance), equilibrium value is made proportional to that quantity (temporary fluctuations being duly attended to). But this is in all essentials and in many details the theory of Ricardo and Marx, and more satisfactory—if we place ourselves on a Ricardian standpoint—than that of A. Smith.[3]

[(b) *Bernoulli's Hypothesis*.] But let us bear in mind that it was the 'subjective' or 'utility' theory of price that had the wind until the influence of the *Wealth of Nations*—and especially of Ricardo's *Principles*—asserted itself. Even after 1776, that theory prevailed on the Continent, and there is an unbroken line of development between Galiani and J. B. Say. Quesnay, Beccaria, Turgot, Verri, Condillac,[4] and many minor lights contributed to establishing it more and more firmly. They all linked price and the mechanism of pricing *directly* to what they conceived to be the fundamental purpose of economic activity, the satisfaction of wants. They all accepted Cantillon's definition of *richesse*, not only as a phrase to be forgotten as soon as stated, or, as in the case of Smith, to be remembered only in order to recommend policies favorable to consumers, but as the starting point of price analysis. Moreover, with all of them, the price phenomenon was rooted in the calculus of pleasure and pain, exactly as it was with Jevons: in this respect they were Benthamites by anticipation, and stronger Benthamites than were to be Bentham's adherents among English economists. Thus, they were not only the forerunners of the 'subjectivists' of the second half of the nineteenth century, but they also sealed that unfortunate alliance between the theory of value and utilitarianism that was to prove so embarrassing a century later.[5] For the moment, however, we shall not go into this any further but instead notice a performance that, besides presenting a number of other points of interest, anticipated the theory of marginal utility still more definitely.

---

[3] Quantity of labor in turn is, in one place, equated to the expense of the laborer's subsistence (*spesa del nutrimento*). Though not Ricardian in form, this passage can be interpreted in a Ricardian sense. But it rather harks back to Cantillon.

[4] *Le Commerce et le gouvernement* (1776), see above, chs. 2 and 3.

In a paper[6] written in 1730 or 1731, Daniel Bernoulli, the eminent scientist whom we have already had occasion to mention, suggested the hypothesis that the economic significance to an individual of an additional dollar is inversely proportional to the number of dollars he already has. Referring this to income rather than, as Bernoulli did, to the monetary value of the total net assets of an individual, we readily identify this additional dollar with what, in the terminology of a later epoch, was to be the marginal dollar, and its significance with what, in the same terminology, was to be its marginal utility, the statistical measurement of which has been attempted by Fisher and Frisch in our own time.[7] No less interesting are the applications to business practice

---

[5] See below, Part III, ch. 3, sec. 1a.

[6] 'Specimen theoriae novae de mensura sortis,' publ. 1738 in the *Commentarii academiae scientiarum imperialis Petropolitanae.* The German translation by Professor Alfred Pringsheim (*Die Grundlage der modernen Wertlehre: Daniel Bernoulli* . . . 1896) contains instructive notes by the translator as well as a very useful introduction by Ludwig Fick. It is, however, highly characteristic of the haziness of our knowledge of doctrinal developments that Mr. Fick not only hailed Bernoulli as a precursor of Gossen, Jevons, Menger, and Walras, but also as one of the first, if not the first, to recognize that value is not an inherent property of things but a relation between a valuating person and the things valued—though *this* was perfectly clear to the scholastic doctors and, in any case, to dozens of eighteenth-century writers who did not know of Bernoulli's paper.

[7] This will be particularly clear on exact formulation. Let x denote an individual's income and y the 'satisfaction' derived from it. Bernoulli's hypothesis then says that

$$dy = K\frac{dx}{x}, \quad \text{or} \quad \frac{dy}{dx} = \frac{K}{x},$$

the factor of proportionality (K), being a constant for every individual, but different for different individuals—the range of variation in the individual K's taking account of individual differences of tastes or intensities of feeling (Bernoulli seems to have attributed the same K to all individuals excepting uninteresting abnormalities, but never mind)—dy/dx is obviously the marginal or final degree of utility, which therefore put in explicit appearance in 1738. As stated by Bernoulli, his fundamental idea was anticipated (1728) by the mathematician Cramer, who offered, however, a different hypothesis about the form of the marginal utility function, viz.,

$$dy = K\frac{dx}{\sqrt{x}},$$

but Bernoulli's hypothesis is, within moderate intervals, quite reasonable though it fails to make use of all we know, or think we know, about the behavior of this function (see below, Part IV, ch. 7).

Since even believers in the measurability of utility or satisfaction will not think it safe to say anything about its behavior in desperate situations, for instance, for in-that Bernoulli made of his hypothesis (op. cit. §§ 15, 16). The underlying idea is that even where the probabilities of gains and losses are strictly calculable—as are, for instance, the chances of loss in sea transport if long experience affords sufficient material—rational action is not determined by the value of these probabilities alone. It is also necessary to take into account the importance to the individual businessman of given gains and losses, which differs of course according to the individual's means, and Bernoulli's hypothesis supplies a method for effecting this. Thus he deduces a criterion by which to decide whether or not it is advantageous for a man to pay a given sum for insuring his cargo, and also a rule by which to evaluate the advantage to be derived from transporting a given quantity of wares in several ships, or from investment of a given sum in several securities instead of in one—important suggestions for a theory of business risks and of investment that even now are not fully exploited. And there may be point in recalling a sentence from Bernoulli's text (op. cit. § 17): 'Precisely because these results agree so well with observed business behavior, it does not seem right to neglect them like unproven statements that are based on insecure hypotheses.' I lament the impossibility of discussing other points[8] about this paper that are of absorbing

---

comes below which the individual cannot survive, we had better exclude such a 'minimum of existence' from consideration. If we call it *a*, total satisfaction derived from an income of the amount *b* may then be represented by the definite integral

$$y = \int_a^b K\frac{dx}{x} = K(\log b - \log a) = K \log \frac{b}{a}$$

[8] Brief allusion to two of them may be permissible, however. The first is that it remained practically unknown to economists until it was noticed by some *who had arrived by themselves at the same or similar ideas*. Fick mentions Hermann (1832), F. A. Lange, *Die Arbeiterfrage* . . . (1865), and especially Jevons, and I have no names to add. This neglect is remarkable owing to Laplace's sponsorship of the Bernoulli formula in his *Théorie analytique des probabilités* (1812), which was of course widely known. The second fact is that Bernoulli's attempt to solve the paradox of the St. Petersburg game is not among the many valuable contributions of his paper, *although it was the primary object of it*. The problem is this. A coin is to be tossed *n* times. *X* promises *Y* to pay \$1 if heads turns up on the first throw; \$2 if heads, having failed to turn up the first time, turns up the second time; \$4 if heads, having failed to turn up the first two times, turns up the third time, and so on. The series of Y's *possible* gains is hence $1, 2, 2^2, 2^3, \ldots 2^{n-1}$. We derive his mathematical expectation of gain by multiplying each of the possible gains by its probability, that is, if the coin be perfect, ½, ¼, ⅛, and so on. It is seen that this multiplication reduces each item to ½ so that, summing up, we get for Y's total mathematical expectation $n/2$, and if *n* is allowed to increase beyond any assigned limit, an expectation greater than any sum we care to mention. Nevertheless, it is the fact that nobody will pay X any considerable sum for it, as the reader can easily find out for himself. Why? Bernoulli thought that all we need to do in order to answer this question is to correct the possible gains by applying his hypothesis to them, which would in fact produce a finite 'moral' expectation in the place of the 'infinite' mathematical one. But this procedure, though not in itself meaningless, does not solve the problem. Neither do, for that matter, the points made by Professor Pringsheim in a footnote to his trans-

interest to the student of the ways of the human mind and of the mechanism of scientific progress.

[(c) *The Theory of the Mechanism of Pricing.*] As regards the theory of the *mechanism* of pricing, there is very little to report before the middle of the eighteenth century. The contributions of even the brightest lights, such as Barbon, Petty, Locke, do not amount to much, and the vast majority of the Consultant Administrators and Pamphleteers of the seventeenth century were content with the kind of theory they found or could have found in Pufendorf. They attended to practical problems of regulative policy, but the analytic side they took largely for granted and were slow to realize the need of rigorous conceptualization and proof. A few examples will illustrate the situation. People were quite familiar with the pattern of monopoly, on which they bestowed an impulsive hatred, and with competition, which they conceived to be the normal pattern without bothering to define it. But as early as 1516, it occurred to Sir Thomas More (*Utopia*, see ch. 3 above) that for competition to prevail it is not necessarily sufficient that a commodity be sold by more than one seller. Prices may fail to fall to the competitive level also if sellers are few, *quod . . . si monopolium appellari non potest . . . certe oligopolium est.*[9] Thus More introduced the concept of oligopoly. We might expect that this hint would have led to closer analysis of the concepts of monopoly and competition, especially in England, where the interminable discussion of monopolies of various types and of restraints of trade of all types—both the restraints that competitors agree on in order to further their common interest, and the restraints monopolists impose upon other people—that preceded and again followed the Statute of Monopolies of 1623/4, furnished all the motive and material one can desire. But there was hardly anything of the kind. Politicians, lawyers, and some businessmen fought 'monopolies' passionately, much as they do today—particularly those of the chartered trading companies—and the attacked interests defended themselves as best they could, also much as they do today. Intellectually, both sides made a poor show, once more much as they do today. Though practical results were achieved and

---

lation, although they, too, are by no means irrelevant. We cannot go further in this subject. But the reader would be much mistaken if he thought that it is without interest to the economist. The theory of games of chance is on the contrary highly important for many problems of economic logic. If proof were needed, a recent book by Professors Morgenstern and von Neumann would supply it (*Theory of Games and Economic Behavior*, 1944). And the first pointer in this direction still stands in Bernoulli's name. In economics it may take 206 years from a first step to the second—just about the same length of time as in the case of the statistical demand curve.

[9] I am indebted to Mr. E. Marz for having drawn my attention to this passage. The fact is curious. Sir Thomas did not only use—and so far as I know coin—the term (oligopoly) that plays so great a role in modern theory, but he used it in order to denote exactly the same thing, and he at once pointed to a feature of it that modern theory was to emphasize—after a lag of about 410 years. Yet the thought is no doubt suggestive and important. And the *Utopia* was very widely read. It is true, however, that this passage does not occur in the English translation of the Latin original.

though the historian of economic thought and policy finds plenty to record,[10] the historian of economic analysis goes from that literature almost empty-handed. Not to neglect any crumbs, however, let us notice, first, the tendency to extend the concept of monopoly beyond the case of a single seller[11] and, second, the rudiments of the argument that monopoly while striving to maximize profits—as we should say—changes the conditions with reference to which this maximization is attempted and so need not necessarily set a higher price than would prevail under competition working under different conditions.[12] We may also mention again Becher's attempt to classify—illogically—market patterns into *monopolium*, *propolium*, and *polypolium*, that is, monopoly, forestalling, and unregulated competition—which according to him is productive of disorganized markets in which every participant is proletarized.

But better things were to follow in the eighteenth century. We shall confine ourselves to the peak achievements of Beccaria, Turgot, and Isnard, and then consider the manner in which the *Wealth of Nations* codified the whole of the value and price theory of the epoch.

Beccaria dealt with value and price in Part IV, Chapter 1 ('Del commercio') of his *Elementi* (publ. posthumously, 1804): the subject stands there pretty much where it was to stand in J. S. Mill's *Principles*. He explains the phenomenon of value, as mentioned already, by utility and scarcity, and then proceeds to investigate the *modus operandi* of a hypothetical market in which wine is bartered for wheat (cf. Marshall's apples and nuts).[13] He recognized clearly that the exchange ratio is indeterminate in the case of isolated exchange (between two individuals) and that determinateness is brought about by competition through the 'higgling of the market': fluctuations must eventually lead to the price at which *quantity demanded equals quantity supplied*. His careful treatment of the exchange of three commodities against one another, in which he insists on the phenomenon (and necessity) of indirect exchange, is particularly satisfactory. This is about as much as the average economist had to say a century later.

---

[10] The reader is referred to Professor Heckscher's *Mercantilism* I, pp. 269 et seq., for a masterly interpretation of that struggle for 'free trade' in the seventeenth-century sense. If he follows this advice, he cannot fail to be impressed by the distressing observation that popular and political discussion of this matter—as of others—shows practically no progress at all.

[11] See Heckscher, op. cit. pp. 273-4, especially the argument of Sir Edwin Sandys (an ardent trust-buster) put forth in the House of Commons debate in 1604, to the effect that the 'name of monopoly . . . is fitly extended to all improportionable paucity of sellers. . . If ten men had the only sale of all the horses in England, this were a monopoly.' Viewed as an analytic effort, this is of course somewhat short of admirable. But it is clear that there is something in what Sir Edwin unsuccessfully strove to express.

[12] Other arguments used for defense turned either on denials of the presence of monopoly—mostly quite true if monopoly be defined strictly, but inconclusive precisely because of this—or on the assertion that in certain cases—especially those of trade with uncivilized countries where protection was an important consideration—monopolistic organization was a practical necessity, or on other points that, whatever their practical weight may have been, are of no interest from the standpoint of analytic technique. One of the best, if not the best, expositions of 'defensive' arguments I have come across is John Wheeler's *A Treatise of Commerce. Wherein are showed the Commodities arising by a well ordered and ruled trade* . . . (1601). This was no doubt 'special pleading' on behalf of the Merchant Adventurers, of which company Wheeler was an attorney. But there is, from our standpoint, no reason for ruling it out on that account.

[13] I hope that we need not take too seriously his proposition that the exchange value of one commodity relatively to the other (the exchange ratio) will be *in ragione reciproca*

Beccaria's performance has been chosen for comment because of its comparative fullness, but it had been strikingly anticipated by Turgot's *Réflexions*, XXXIII-XXXV (written in 1766, published in 1769-70). After having deduced trading (commerce) from *besoins réciproques*, Turgot, too, touches upon the case of isolated exchange and then introduces the determining force, competition. His description of the market mechanism is very similar to that of Böhm-Bawerk (see below, Part IV, ch. 5, sec. 4). The resulting market price (*prix courant*) is then made to vary under the impact of forces acting through demand or supply. The crowning achievement of the epoch in this line of analysis is Isnard's.[14] In his not otherwise remarkable book there is an elementary system of equations that—barring the difference in technique—describes the interdependence within the universe of prices in a way suggestive of Walras.

[(d) *Codification of Value and Price Theory in the* Wealth of Nations.] A. Smith's 'chief work was to combine and develop the speculations of his French and English contemporaries and predecessors as to value.'[15] Also, it is

---

delle loro quantità. Possibly there is a connection between this and his friend Verri's hyperbolical demand law, which however is not open to the same objection but, on the contrary, must be recorded as the first attempt to give a precise form to the demand curve: if p be price (in money), q quantity, and c a constant, then, according to Verri's law, $pq = c$.

[14] Achille Nicolas Isnard's *Traité des richesses* appeared in 1781, and thus forms no part of the material 'codified' by A. Smith. There is, however, a question of the latter's influence upon the former. Isnard's treatise, also the contribution mentioned in the text, *could* have arisen from a perusal of the *Wealth of Nations*. Isnard does not mention A. Smith, however, unless, indeed, I have overlooked the reference. The title of the book is included in Jevons' list of mathematical writings, which is how I came to know of it. I have found no traces of its influence.

[15] A. Marshall, *Principles*, 4th ed., p. 58. The reader will realize that the opinion of a workman such as Marshall is worth a ton of philosophizing by less workmanlike people, and we cannot do better than use that dictum of a master of economic theory as a motto. Also, the reader will realize that even Marshall, whose admiration for Smith was unbounded, does not go beyond what our own term 'codification' implies. Though he was far from attributing to Smith any original ideas, he nevertheless arrived at an estimate of the performance that seems much higher than ours. One reason for this may be that he was speaking of a brother—for as has been and will be emphasized, there are many similarities in the performances and in the historical positions of the two. Another may be that he was speaking of a countryman—for Marshall was very insular. A third one may be that he was speaking of a fellow liberal—for Marshall, too, was a strong free trader. But whatever the reason, the reader should

quite true that he made 'a careful and scientific inquiry into the manner in which value measures human motive,' that is to say, I take it, that he made exchange value (price or, at all events, relative price) the centerpiece of a primitive system of equilibrium. But he was not, as Marshall held, the first to do so; moreover, in codifying, he dropped or sterilized many of the most promising suggestions contained in the work of his immediate predecessors. Of course, he may not have known Turgot's *Réflexions*, and he cannot have known Beccaria's *Elementi*: Pufendorf and then Cantillon, Harris, Locke, Barbon, Petty—these last five are mentioned by Marshall—and Quesnay were presumably his principal guides so that his 'subjective' performance was greater than was his 'objective' achievement. But he 'developed' this material less successfully than had Turgot and Beccaria. The blame is at his door for much that is unsatisfactory in the economic theory of the subsequent hundred years, and for many controversies that would have been unnecessary had he summed up in a different manner.

The reader should refresh his recollection of the Reader's Guide presented above.[16] A. Smith's exposition in the first Book surges purposefully up to the phenomenon of price and down again into the component parts of commodity prices, which components are the cost and income categories, wages, profit, and rent. This is, to repeat, a primitive way of describing the universal interdependence of the magnitudes that constitute the economic cosmos; but it is an effective way. Critics who did not understand that the theory of price is but another name for theory of economic logic—including, among other things, all the principles of allocation of resources and of formation of incomes—blamed him for having adopted the narrow point of view of the businessman. Other critics who did not understand the nature of a system of interdependent magnitudes accused him of circular reasoning. His shade easily wins out against these and other criticisms. It is this part of his performance that constitutes his chief merit in this field. There are others. As primitive but as distinctly visible as is his concept of universal interdependence is his concept of equilibrium or 'natural' price. This equilibrium price is simply the price at which it is possible to supply, in the long run, each commodity in a quantity that will equal 'effective demand' *at that price*. This again is the price that will, in the long run, just cover costs. And these, in turn, are equal to the sum total of the wages, profits, and rents that have to be paid or imputed at their '*ordinary or average rates*.' Thus, we also get a glimpse of Marshall's distinction between short-run and long-run phenomena, A. Smith's market price being essentially a short-run phenomenon, his 'natural' price a long-run phenomenon

---

observe that, so far as Marshall's very brief comments enable us to judge, there is no difference as to the facts of the case except this: Smith may certainly be said, in a sense, to have 'developed' existing doctrines of value and price; but whereas Marshall approved unconditionally of the manner of this 'development,' I have some fault to find with it.

[16] [After writing this, J. A. S. apparently removed several pages on A. Smith, including the Reader's Guide, from the manuscript. This material has been restored by the editor and is to be found in ch. 3, sec. 4e.]

—Marshall's long-run normal. 'It is all in A. Smith' was a favorite saying of Marshall's. But we may also say: 'It is all in the scholastics.' There is no theory of monopoly. The proposition (Book 1, ch. 7) that 'the price of monopoly is upon every occasion the highest which can be got' might be the product of a not very intelligent layman—taken literally, it is not even true. But neither is the mechanism of competition made the subject of more searching analysis. In consequence, A. Smith fails to prove satisfactorily his proposition that the competitive price is 'the lowest which the sellers can commonly afford to take'—to the modern reader it is a source of wonder what kind of argument he took for proof. Still less did he attempt to prove that competition tends to minimize costs, though it is evident that he must have believed it.

But what was A. Smith's theory of value in the narrow sense of the phrase, meaning his views on the problem of causal explanation of the phenomenon of value? Since during the subsequent century economists were much interested in that problem, they eagerly discussed Smith's views about it and for this very reason we cannot pass it by. In itself, the answer is plain enough.

First of all, if the reader will look up the last paragraphs of Book 1, Chapter 4, he will be able to satisfy himself of two things. On the one hand, A. Smith declares there that he is going to inquire into the rules which 'men naturally observe in exchanging' goods 'either for money or for one another.' This means that he was not primarily interested in the problem of value in the sense just defined. What he wanted was a price theory by which to establish certain propositions that do not require going into the background of the value phenomenon at all. Evidently this was also Marshall's opinion. On the other hand, having distinguished value in use and value in exchange, he dismisses the former by pointing to what has been called above the 'paradox of value'—which he evidently did believe to be a bar to progress on this line—thereby barring, for the next two or three generations, the door so auspiciously opened by his French and Italian predecessors. No talk about his 'recognizing the role of demand' can alter this fact. Second, in Book 1, Chapter 6, A. Smith expressly states: 'Wages, profit, and rent, are the three *original* [my italics] sources of all revenue as well as of all exchangeable value.' If words mean anything, this is conclusive. His theory of value was what later on came to be called a cost-of-production theory. This is indeed the opinion of many students. But, third, the matter is complicated by the fact that a very large number of passages in the *Wealth of Nations* seem to point to a labor theory of value or rather to several.[17]

In Book 1, Chapter 5, of the *Wealth of Nations* occurs the proposition: 'The real price of everything, what everything really costs to the man who wants to acquire it, is the toil and trouble of acquiring it'—one of those treacherous platitudes that may mean anything and nothing. On the face of it, however, it indicates a tendency to base the value phenomenon upon the irksomeness or disutility of work, or to adopt a labor-disutility theory of value. This theory, however, may be discarded, because A. Smith makes no use whatever of it. Again, at the beginning of Book I, Chapter 6, Smith produces the famous example about the beaver: 'if . . . it usually costs twice the labour to kill a beaver which it does to kill a deer,' one beaver would naturally sell for as much as two deer. There it is quantity of labor that 'regulates' value and not toil and trouble, which is, of course, not the same thing. No doubt is possible but that this passage is the root of Ricardo's and Marx's labor-quantity theories of value. But A. Smith limits this theory to 'that early and rude state of society which precedes both the accumulation of stock and the appropriation of land,' which, interpreted charitably, means that competitive prices of commodities will, in equilibrium, be proportional to the labor entering into their production if the labor is all of the same 'natural' quality and if there are no other scarce means of production. This is true but does not in itself constitute a labor-quantity theory, or any labor theory, of value, because, for this special case, all theories of value would arrive at the same result. Finally, as we have already had occasion to notice, A. Smith (Book I, ch. 5) considers the quantity of labor a commodity can command in the market the most useful substitute for its price in money, that is to say, he chooses labor for *numéraire*. On principle, there can be no objection to this decision, which in itself no more commits him to a labor theory of value than the choice of oxen for *numéraire* would commit us to an ox theory of value. But he tries to motivate his decision by so many arguments that seem to claim deeper meaning for it—such as that 'labour alone . . . never varying in its own value, is alone [sic] the ultimate and real standard' of the values of all commodities or that 'it is their real price' or 'the only universal as well as the only accurate measure of value,' which are all wrong—and seems himself so little clear about what is and what is not implied in choosing something for *numéraire* that it is almost excusable if many later economists misunderstood what he actually did mean and that they, among them Ricardo,[18] accused him of having confused the quantity of labor that enters a commodity with the quantity of labor it will buy. This indictment fails, however, and it is important that it does, for it amounts to accusing Smith of an absurdity: taking what a commodity exchanges for, no matter what it is, as the *explanation* of its value would be one of the worst slips in the history of theory. It should be added that, if choosing an hour's or day's labor as the unit in which to express prices does not imply accepting a labor theory of value, no more does emphasis upon labor's role in production or upon labor's claims or wrongs. As has been mentioned already, there is plenty of this in the *Wealth of Nations*, much of it, perhaps, inspired by Locke. 'The produce of labour constitutes the natural recompence or wages of labour' (Book I, ch. 8). It is the laborer who raises the crop and the landowner, having appropriated the land, demands a share of it. Profit makes a second deduction from the 'produce of labour.' To this day, it has remained difficult to make the philosophy-minded see that all this is completely irrelevant for a theory of value—considered not as a profession of faith or as an argument in social ethics, but as a tool of analysis of economic reality.

---

[17] It is still not sufficiently recognized that the term labor theory of value covers several distinct meanings. The subject has, however, been exhaustively dealt with by H. J. Davenport, *Value and Distribution*, 1908.

---

[18] Ricardo did not misunderstand him always, however. Ricardo also argued that the exchange value of labor is no more exempt from fluctuations than is the exchange value of anything else. But this is relevant only with regard to making labor a *numéraire* that is to function over time.

4. THE QUANTITY THEORY

It will not surprise the reader to learn that the *effects* of the violent price revolutions of the fifteenth, sixteenth, and seventeenth centuries should have been zealously discussed. But it might surprise him to learn that there was any question about their causes. For debasement of the currency—devaluations by governments as well as fraudulent clipping of coins by individuals—and the torrent of American gold and especially silver were before everyone's eyes; and not even the most sophisticated theorist of today could find fault with the obvious diagnosis, seeing that the monetary units newly created by either the debasement of the coinage or the influx of the American silver were very promptly spent, while the very wars on which they were mainly spent greatly interfered with production. Nevertheless, though it is probably possible to find early arguments that more or less distinctly imply this obvious diagnosis,[1] it seems to be the fact that no explicit, full, and—so far as it went—theoretically satisfactory presentation of it appeared before 1568, when Bodin published his *Response* to the *Paradoxes sur le faict des Monnoyes* (1566) of M. de Malestroict. (There is a translation of Bodin's *Response* in A. E. Monroe's *Early Economic Thought*.) On the strength of this, he is universally voted the 'discoverer' of the Quantity Theory of Money. Since the matter has received attention quite out of proportion to its importance, we shall go into it briefly ourselves.

---

[1] I say 'probably' because I do not myself know of any clear instances. The cases mentioned by Professor Seligman (article, 'Bullionists,' *Encyclopaedia of the Social Sciences*) are not convincing. Some historians who trace this kind of 'quantity theory' to the Middle Ages and even to the Roman jurist Paulus have misunderstood the word *quantitas*, which must not be translated by 'quantity' (see above, ch. 1). The best example I can mention—but it followed by a year Bodin's work, which I am about to mention in the text—is in the *Summa de tratos y contratos* of Tomás de Mercado (1st ed. 1569; ed. used 1571). By the end of the century, recognition of the effects on prices of the American silver was widespread, if not universal, as well it might have been. Luiz Valle de la Cerda (*Fundación*, 1593; *Desempeño*, 1600) called the price rise the 'efecto muy natural de la rapida multiplicacion de los signos y moneda.' The words 'very natural' in this passage have nothing to do with natural law but simply stand for 'indubitable' or 'obvious' The contrary impression, voiced by Professor Hamilton, viz. that the influence of the inflow of silver upon prices was being persistently ignored or denied, seems due to the facts that many later authors had reasons for emphasizing the other factors in the price rise which were operative, especially in the case of Spain, and also that the common run of writers was then, as it is now, quite impervious to even the simplest economic truths.

[(a) *Bodin's Explanation of the Price Revolution.*] Jehan Cherruyt de Malestroict had argued that the universal rise in prices was due to debasement and that, expressed in full-weight coin, prices had not risen. Bodin replied—and then repeated in *Les six livres de la République*, 1576—that this argument overlooked the influence of American silver. The price revolution, according to him, was due to (1) the increase in the supply of gold and silver; (2) the prevalence of monopolies; (3) depredations that reduced the stream of available commodities; (4) the expenditure of kings and princes on the objects of their desires; and (5) the debasements that were the only factor considered by his opponent. He added, moreover, that the first cause was the most important one. The reader will observe that this analysis needs but little readjustment or generosity of interpretation to be a correct diagnosis of the historical case as it presented itself in 1568. Even as regards general theoretical content, it is superior to much later work. In fact, Bodin's analysis escapes several of the typical objections that were to be raised against the quantity theory in the nineteenth century. But does it state or imply this theory?

The question may seem surprising, but it is well worth asking. Let us embrace, for a moment, uncompromising metallism and consider the case of perfect gold monometallism—gold metallism such that gold can move freely in and out of the monetary system—from this standpoint. Gold being a commodity like any other, the value in terms of commodities of the golden monetary unit will fall, other things being equal, if gold production increases, just as the price of eggs will fall, other things being equal, if egg production increases. Any rise in prices in terms of gold that may occur is here explained as a consequence of increased supply. Let us note that the extent of this fall (in the value of gold) will simply depend upon the shape of the demand schedule for gold as a commodity in terms of some other standard, and that the operative 'quantity' in question is the total amount of the increase. In consequence, there is no reason to suppose that, however equal the other things, the fall will be proportional to the increase. It will be seen that no special hypothesis enters into the argument, which flows smoothly from the metallist basis and would have been accepted by the scholastics as a matter of course. But recognition of the relevance of 'quantity' to the value of money in this sense and for this reason has no more to do with the Quantity Theory of Money than that the word quantity occurs in both arguments. And no more than this is required for Bodin's argument or, let us add at once, for that of A. Smith.

[(b) *Implications of the Quantity Theorem.*] In order to make this clear, let us look at the same case from the standpoint of the quantity theory. To facilitate exposition we shall assume that there is an absolutely fixed collection of goods that must be sold for whatever money buyers have, and that these buyers feel compelled to spend promptly all of whatever money they have upon that collection of goods. Also we shall henceforth speak, instead of the quantity *theory*, of the quantity *theorem*, because it is not a complete theory of money but merely a proposition about the exchange value of money. Keeping, then, everything else severely as it is, we let gold production increase. As in the simple metallist argument, we infer that this will make the unit of gold less valuable, that is, raise all prices in terms of it. The reason for this is the same as before so far as that part of the increase is concerned that goes into industrial uses. But that part of the increase which spills over into circulation now operates in a different way and produces a fall in the exchange value of the monetary gold—a rise in commodity prices—for a different reason: the fall, under our highly artificial assumptions, is exactly proportional to the increase in the quantity of the *monetary* gold stock; and the immediate reason for this is not the fall in the commodity value of the gold—which is relevant indeed but only at one remove, that is, by virtue of the fact that it will determine the extent to which the quantity of monetary gold will be increased—but the increase of the quantity of coins per se. It is the increase in *this* quantity which, the purchasing power of the total monetary stock remaining constant, is the immediate cause of the resulting fall in the exchange value of the monetary unit. And this fall will be the same as if this stock, without being increased, had been split into units of smaller gold content, *because* in either case there is now less of every commodity per coin. Operation of the new gold in the *commodity* use may be likened to the effects of adding workers of the same skill to a given plant and equipment. Operation of the new gold in the *monetary* use may be likened to the effects of replacing the working force operating a given plant and equipment by more workers of proportionately less skill. Thus the quantity theorem does three things: first, it recognizes the fact that the monetary function will affect the value of the commodity chosen for money and is a logically distinct—though not independent—source of the exchange value of gold (this, of course, we can recognize without committing ourselves to the next steps); second, it recognizes that the mechanism that determines the value of gold in circulation is different from the mechanism that determines the value of the industrial gold or of any other commodity; third, it offers a specific schema—very primitive but also very simple—of that mechanism. The apparent difficulty of this really simple matter is due to the facts that in the case of perfect gold monometallism the two different mechanisms must, of course, produce the same values of gold in the monetary and in the industrial sphere; and that the influences of an increase in gold production upon the commodity value and upon the monetary value of gold so intertwine that we do not see either quite clearly. But it is one of the strong points of the quantity theory that it can be applied to the case of paper money without any auxiliary construction. And in this case—when there is no commodity value of the material to cause ambiguity about what quantity we mean and what *modus operandi* we attribute to it—all becomes perfectly clear. This logical affinity of the quantity theorem with theoretical cartalism should be borne in mind: the theorem essentially amounts to treating money not as a commodity but as a voucher for buying goods, though not everyone who does consider money in this light need accept the specific schema offered by the quantity theorem. It is the more important to remember this point because later developments tended to obliterate it.

There is no trace of considerations of this type in Bodin. But there is in

Davanzati (1588, see above, sec. 2), who confronted the mass of commodities with the mass of money—stock with stock—and would have to be credited with superior formulation of the quantity theorem in its most primitive form even if we interpreted Bodin's argument in the same sense. Subsequent advance on this line was slow. Mere recognition of the effect upon prices of American gold and silver imports or of any increase in a country's stock of gold and silver, of course, soon became commonplace. It is not always easy to tell from the uncouth writings of the less literate 'mercantilists' what it was they had in mind, but some of them, especially Malynes and Mun (see below, ch. 7), tried, I think, to convey the genuine quantity-theory idea—though in a quite rudimentary form—while others, perhaps the majority, were content with 'simple metallism.'[2] However, Davanzati at long last found a successor in Montanari (1680), and in England instances become frequent in the second half of the seventeenth century. Among these Briscoe (1694) deserves special notice,[3] because he was the first, so far as I know, to write an equation of exchange in the unsatisfactory form: stock of money equals prices times real income.[4] In the course of the eighteenth century it was the genuine quantity theorem that, sometimes in the crudest possible form, became a commonplace for many of the leaders. It is taken for granted by Genovesi, Galiani, Beccaria, and Justi, and Hume reasserted it with an emphasis that was hardly necessary (1752). All the more significant is it that A. Smith did not definitely commit himself to more than simple metallism.

---

[2] Malynes says categorically: 'Plentie of money maketh generally things deare' (*Tudor Economic Documents* III, 387), which at least admits the interpretation above. Mun's case is similar. An illustration of a recognition of the effect of increased 'treasure' that does not imply the genuine quantity theory idea is in Sir Robert Cotton's speech on the 'Alteration of coine,' 1626: 'Gold and silver . . . are Commodities valuing each other according to the plenty or scarcity; and so all other Commodities by them' (Reprinted in McCulloch's *Scarce and Valuable Tracts on Money*). It should be observed, however, that what we have called the theory of 'simple metallism,' i.e. theoretical metallism without the specifically quantity-theorem element in it, is sufficient to protect 'mercantilists' from the indictments that in general they failed to perceive the effect of their beloved gold and silver imports upon prices and that, whenever they did, they really refuted their argument for export surpluses. The specific or genuine quantity theorem is not necessary for perceiving that effect. And the proposition that export surpluses are desirable because they will bring 'treasure' into the country, whatever its demerits may be, is not refuted by the argument that this inflow of gold and silver will raise prices and thus stop the exports. For, first, much treasure can be collected on the way to this consummation. Second, the treasure imported would have that effect only if it entered circulation, which was not always the idea. There are also other possible lines of defense that will appear as we go along.

[3] Montanari and Briscoe are discussed in sec. 2, above.

[4] Since this is the first time that we meet this analytic tool, it is convenient to make at once a few comments that will be of help to the beginner. Other comments will be added later (Part IV, ch. 8). The equation of exchange (also called the Fisher equation after the most eminent of those modern economists who used it as a starting point of the theory of money) is now usually written: $MV = PT$, where M means quantity of money, V velocity, P price level, and T physical volume of transactions. Briscoe's equation becomes identical with this by putting $V = 1$. The first thing to note is that M, V, P, T can each of them be given any of a number of different meanings, which must, of course, be made to correspond; for instance, M may mean only full-weight coin, or only legal tender (including government paper), or only legal tender plus bank notes minus the reserves held against them, or legal tender plus

But Briscoe's equation of exchange was already obsolete when he published it: [5] a major step forward had been taken before. The most primitive way of looking at the relation between quantity of money and prices, but to the primitive mind the most natural way, is to compare a stock or fund of money with a stock or fund of goods that are supposed to be exchanged against one another. The next idea to occur to one's mind, when one comes to think of it more carefully, is that this stock of goods is a rather doubtful entity: the total of the coins may indeed be thought of as a definite stock of pieces that, unless demonetized or exported, are also permanent; but the commodities that are being currently exchanged for these coins are not each time the same individual pieces—the individual units of bread and wine and cloth and so on disappear from the market for good and are currently replaced by other units to meet, on the next market day, the same coins again. Therefore, comparison is between a stock and a flow. The obvious way to reduce them to comparability is to choose a unit period and to multiply the stock by a coefficient that tells us how often in this period the stock meets the flow, that is, how often per period the money does what the goods can do only once. The problem is greatly simplified, though its solution loses much in value, if we assume that all the coins are spent—none held back—and spent only once each market day—equal quantities of all goods being offered on each day—and that there are no other transactions: then the 'velocity' or 'rapidity of circulation' of money will equal the number of market days per unit period. If this number be 12 per year, the stock of money will support the same price level that a stock 12 times as great would support with but a single market day per year. *Taken in this sense*, 'velocity' is peculiar to money and neither has nor can have any analogue in the world of commodities.[6]

---

bank notes plus demand deposits minus the reserves of all banks. Similarly, T may mean all transactions, or only the transactions incident to production and distribution, or only the transactions consisting of income payments and income expenditure on consumers' goods—the last being the definition adopted by Briscoe. Second, in the case of V, there is a distinction of a different kind to be made that is of the utmost importance. On the one hand, we may put $V = PT/M$ *by definition*. If we do this, then the equation of exchange must evidently hold always and under all circumstances. It is, as we say, a mere tautology or identity and should really be written $MV \equiv PT$. But we need not do this. We can also define V independently of the three other magnitudes, for instance, by the number of times a dollar *can* on the average be paid to an income receiver in the institutional arrangements of a given society.

[5] Still more obsolete was, of course, a similar equation published in 1771 by H. Lloyd in his *Essay on the Theory of Money*. Of this essay I only know the Italian abstract appended to Verri's *Meditazioni* in Custodi's *Scrittori Classici*.

[6] I have taken space I can ill afford to spare to explain this matter in its most elementary aspect because it is essential for the reader to realize how it presented itself

Perception of this fact and its insertion into the analytic engine was mainly the achievement of three men—Petty, Locke, and Cantillon. Its importance warrants an inquiry into the manner in which the 'discovery' was made.

Neither Petty nor Locke proceeded in the logical way, that is to say, by deducing the phenomenon of velocity from the nature of money—the way adumbrated above. They ran up against it in the course of their attempts to answer a practical question which they thought important. This question was: what is the quantity of money that a given country needs? Hume ('Of Money' in *Political Discourses*, 1752) seems to have been the first to show clearly and explicitly that on the level of pure logic this question has no meaning—on the one hand, any quantity of money, however small, will do in an isolated country; on the other hand, with perfect gold currency all round, every country will always tend to have the amount appropriate to its relative position in international trade. But in the sixteenth century people thought differently, and practical sense may in fact be imparted to that question by adding: at the prevailing level of prices. Thus amended, the problem was to determine the requirements of internal circulation under given conditions of time and place with a view *either* to support up to a point *or* to combat beyond that point the 'mercantilist' policy of enforcing gold and silver imports.

The task was primarily of a statistical nature. Petty tackled it from the angle of income payments, that is to say . . . [unfinished; the two following paragraphs are taken from the brief early treatment on money described in the appendix and hence do not connect exactly with what precedes.]

There is one more point. From the standpoint of the theorist it is always a 'major event' when an important concept is made explicit and workable, although it was—this is the usual case—implicitly present in previous arguments. The shadow of Velocity of Money may be detected in Davanzati. But it did not acquire substance until the last decades of the seventeenth century. This was a purely English achievement. We know already of Sir William Petty's exploit in the field. The other sponsor was Locke (in *Some Considerations*, 1692). He approaches the phenomenon by way of the cash balances which various classes of people are under the practical necessity of holding. The effects of variations in the velocity on prices are not pointed out directly, though they may be said to come in indirectly through the action of the rate of inter-

---

in the beginnings of analysis: every further step leads into mist, ambiguity, difficulty, but that first one is perfectly clear and simple. I take the opportunity to add two points to our knowledge about the equation of exchange. Look again at our example: a definite number of coins settling by payment in specie the commodity transactions of the twelve market days. Now, first, these twelve market days represent a social custom, an institutional arrangement that individuals are powerless to alter. No coin can, under our assumption, have a greater velocity. But what if holders of some of the coins, on any given market day, refuse to spend all the coins they hold? We may then say, of course, that the coins that are not spent on any given market day or are not spent on any of them have a smaller velocity or even the velocity zero. But we may also say . . . [note unfinished].

est on idle balances.[7] Cantillon, who, so far as I know, was the first to speak of *vitesse de la circulation*, was also the first to state in so many words that increase in the velocity of money was equivalent to increase in its quantity. He also drew the conclusion that measures calculated to decrease velocity will counteract the effects of inflation. Neither Hume nor Smith added anything of importance.

It will be seen that the concept evolved from the first on both the lines that were followed in its later development. Petty and Locke used the cash balance approach, Cantillon the turnover approach. Locke and Cantillon clearly envisage not only velocity in the strict sense but also the rate of spending. Owing to the prominence that the related concept of Propensity to Consume has gained in connection with the multiplier analysis, it may be interesting to add two examples to show that this concept, too, was perfectly familiar to the economists of that epoch. As we already know, Boisguillebert (*Dissertation sur la nature des richesses*) pointed out that a coin in the hand of a very small trader is spent much more promptly than a coin in the hand of a rich man who is more likely to shut it up in his *coffres*—the hoarding rich are evidently no discovery or invention of the last ten years. And Galiani (in the second *Dialogue sur le commerce des blés*) drew a distinction between the propensity to consume of the farmer, who saves and hoards, and of the artisan who promptly spends (*dissipe*).

5. Credit and Banking

We know that the late scholastics were familiar with practically all the essential features of capitalism. In particular, they were familiar with stock exchanges and money markets, with lending and banking, with bills of exchange and other instruments of credit.[1] So far as the phenomena to be interpreted are concerned, the bank note is the only one that was added in the course of the sixteenth century—thrusting into the background for about two centuries the oldest form of what came to be called 'bank money,' the transferable deposit: even Hume, as late as 1752, spoke of 'this new invention of paper.' Yet the bank note, at least in one of its early forms, should not have struck him as a novelty: the note that was a goldsmith's receipt for gold actually deposited was really nothing but a device for increasing safety and convenience in handling one's money, and fitted in perfectly with older ideas. New, however, were the practices of which the bank note became the chief vehicle, and the importance it acquired in consequence. Daniel Webster, in 1839, made note issue the defining trait of a bank. These practices and the phenomena attending them quickly produced an interesting *analytic* development.

---

[7] On this point as well as on this subject as a whole, see M. W. Holtrop, 'Theories of the Velocity of Circulation of Money in Earlier Economic Literature,' *Economic History, Supplement to the Economic Journal*, January 1929, and Professor Marget's *Theory of Prices*, vol. I, *passim*.

[1] See above, ch. 2. The reader's attention is once more called to Professor Usher's book there mentioned (*The Early History of Deposit Banking in Mediterranean Europe*, 1943). Also see Van Dillen, *History of the Principal Public Banks* (with extensive bibliography), 1934.

The point to grasp is this. When beholding the nascent institutions of capitalism, the scholastic doctors and their laical successors did not experience any difficulty in interpreting them and in fitting them into their metallist theory of money. This analytic task was facilitated by their command of the conceptual apparatus of the Roman law. Observing sales contracts that provided for deferred payment, they readily analyzed them into a sale proper and a loan of money. The deposit of money, being a *depositum irregulare,* conferred ownership on the receiver of the deposit: the scholastic fathers might even have deduced that the receiver was not bound in law or morals to keep deposits of this nature in a vault, because he owed only *tantumdem in genere,* that is, as much of the same kind as he had received. Moreover, if a business connection made *A* the debtor of *B* and concurrently *B* the debtor of *A,* they might—within limits—'compensate,' and were to be held responsible only for the difference; and this principle might then be extended to multilateral and interlocal clearing of debts without the use of actual cash. The upshot is that for the scholastics neither lending in the usual sense of the word nor the giving or receiving of credit in the course of commodity trade or any other transactions had really anything to do with the monetary system and its working: these things involved the use of money, no doubt, but in no other sense than does buying for money or making a gift in money or paying taxes in money.

But this of course is not so. 'Credit' operations of whatever shape or kind do affect the working of the monetary system; more important, they do affect the working of the capitalist engine—so much so as to become an essential part of it without which the rest cannot be understood at all. This is what economists discovered in the seventeenth century and tried to work out in the eighteenth: it was then that capitalism was analytically discovered or, as we may also say, discovered or became analytically conscious of itself. Let us see how this discovery came about and how far it went. Two lines of advance are distinctly visible.

[(a) *Credit and the Concept of Velocity: Cantillon.*] The first of these might have been taken by the scholastic doctors themselves, had scholastic economics developed from its own bases throughout the seventeenth and eighteenth centuries. That is to say, a strictly metallist conception of money invited, if it did not absolutely enforce, the attempt to draw a sharp dividing line between money and the legal instruments that embody claims to money and operations in money, *and to bring the latter into the picture by means of auxiliary constructions* for which the legal concepts alluded to above offered suggestions. To some extent such a course is always possible,[2] in our case even more so than usually. The auxiliary construction that is needed consists in an extension of the concept of velocity. The banker who issues notes in excess of his cash holding is not thought of as creating or increasing means of payment, let alone 'money.' All he does is to increase the velocity of that cash, which by proxy, as it were, effects many more payments than it could settle by going from hand to hand; and the same applies, of course, when he directly lends part of the cash deposited with him. The clear perception of the truth that a bank note and a checking deposit are fundamentally the same thing is in fact one of the strong points of this theory. Thus money remains very strictly defined. Credit, particularly bank credit, is merely a method of using it more efficiently. I cannot stop to show, but the reader may easily see for himself, that most phenomena that go under the heading of credit *can* be described in this way. Government paper money may then either be included with full-weight coin in the total of the quantity of money or else construed as a government debt—that is, as a promise to pay in coin at some time or other. The latter view predominated, and throughout the nineteenth century there are instances of governments issuing notes with the legend: 'This note is part of the government's floating debt,' suggesting an analogy with treasury bills, especially when the notes carried interest, as they not infrequently did.

---

[2] To quote two instances of incomparably greater importance: the so-called Ptolemaic system of astronomy was not simply 'wrong.' It accounted satisfactorily for a great mass of observations. And as observations accumulated that did not, at first sight, accord with it, astronomers devised additional hypotheses that brought the recalcitrant facts, or part of them, within the fold of the system. Again, classical physics accounted satisfactorily for all the known facts until it received a severe jolt through

The outstanding authority for this theory is Cantillon, who carried it out in detail and with as much common sense as brilliance. His bankers are essentially intermediary lenders of other people's money. They lend the deposits they receive, and by so doing speed up things and lower the rate of interest. The logical difficulties that lurk in this apparently simple statement are somewhat reduced by his emphasis upon the case in which bankers only lend what depositors, for the time being, do not need—the case of time deposits, as we should say—so that a given sum of money only does one service at a time. Moreover, we must not forget that Cantillon lived in an environment where, wholesale trade apart, payment in specie was the overwhelming rule, so that people incessantly fetched and brought bags of coin to and from the bank; and where it was as usual to acquire a deposit by actually depositing coin as it is now to acquire one by borrowing or by transfer from another borrower. At any rate his teaching stands at the fountainhead of what remained official banking theory practically up to the First World War. Galiani and Turgot—independently or not—held the same doctrine. So did innumerable minor lights, such as Justi, and 'business economists,' such as Marperger.

But, to say the least, this is not the only way of interpreting the facts of banking practice. Even the banker who lends by paying out actual money deposited with him does more than collect it from innumerable small puddles, where it stagnates, in order to hand it to people who will use it. He lends

---

the negative result of Michelson's experiment (1881). But this did not induce physicists to abandon the classical system at once. Instead, the Michelson effect was built into it by means of a special hypothesis *ad hoc* (H. A. Lorentz, 1895); and this hypothesis satisfied the profession until the emergence of Einstein's theory about a quarter of a century after Michelson's experiment. *Si licet parva componere magnis*. . .

the same sums over and over again *before the first borrower has repaid:* that is to say, he does not merely find successive employments for the sum entrusted to him, but many employments which that sum then fills simultaneously. If he lends by paying out notes—or by crediting the sum lent to the borrower in a checking account—for which his cash holding acts merely as a reserve, the same fact stands out still more clearly. And so it does if he lends coins he received as a deposit, which the depositor proposes to use exactly as he would have used the coins had he kept them.[3] There surely must be other ways of expressing these practices than by calling these bank notes embodiments of velocity of circulation—a velocity so great that it enables a thing to be in different places at the same time. More important than this terminological inconvenience is the fact that the velocity of circulation in the technical sense of the word is not increased at all: the banker's loans do not alter the 'stations' through which a unit of purchasing power has to pass, or abridge the time it takes in passing them, or—in themselves—affect people's habits of holding certain amounts of what *they* consider to be ready cash. Therefore it may, perhaps, seem more natural to say that bankers increase not the velocity but the quantity of money—or of those means of payment that, within limits, serve as well as money if one wishes to reserve this term for coin or coin and government paper. This accords perfectly with practice—borrowers do feel that they get additional liquid means that are normally just as good as money. Banks are no longer said to 'lend their deposits' or 'other people's money,' but to 'create' deposits or bank notes: they appear to manufacture money rather than to increase its velocity or to act—which is a completely unrealistic idea—on behalf of their depositors. In any case, it is clear and actually beyond dispute that what the banker does with money cannot be done with any other commodity—or, as some of us would prefer to say, with a commodity—for no other commodity's quantity or velocity can be increased in this way. The only answer to the question why this is so is that there is no other case in which a claim to a thing can, within limits to be sure, serve the same purpose as the thing itself: you cannot ride on a claim to a horse, but you can pay with a claim to money. But this is a strong reason for calling money what purports to be a claim to legal money, provided it does serve as means of payment. As a rule, an ordinary bill of exchange does not so serve; then it is not money, and belongs to the demand side of the money market. Sometimes, however, certain classes of them do; then, according to this view, they are money and form part of the supply on the money market. Bank notes and checking deposits eminently do what money does; hence they are money. Thus credit instruments, or some of them, intrude into the monetary system; and, by the same token, money in turn is but a credit instrument, a claim to the only final means of payment, the consumers' good. By now this theory—which of course is capable of taking many forms and stands in need of many elaborations—may be said to prevail.

---

[3] Professor Rist (*History of Monetary and Credit Theory from John Law to the Present Day*, 1940, ch. 1), who may be cited as, perhaps, the leading modern exponent of the Cantillon view, rightly insists that there is no 'mystery' about credit and that talking about the 'mystery of credit' is often indicative of hazy thinking. But there is a question of interpretation and there is a point requiring elucidation. Suppose it occurs to the check-room attendant of a restaurant to rent out the coats deposited with him while their owners are having their meal. This may, upon occasion, cause a difficult situation for the attendant, but there is no *logical* difficulty about it. But suppose he is a wizard, and performs the feat of making it possible for two people—the owner and the hirer—to wear the same coat at the same time. Surely this would stand in need of explanation—and this is exactly what happens in the case of banking, if bank notes and bank deposits are really, as Professor Rist says, nothing but 'material embodiments of the velocity of circulation.' May I use this opportunity to add that, so far as any implications as to policy are concerned, I quite agree with him; that personally I feel nothing but admiration and gratitude for the brilliant services he has rendered in more than one country to the cause of what, like him, I believe to be sound finance? I hold no brief for land-bank schemes or any of their modern counterparts. I am interested in a mere point of theory and, at most, a few points of past history.

[(b) *John Law: Ancestor of the Idea of a Managed Currency.*] Manufacture of money! Credit as a creator of money! Manifestly, this opens up other than theoretical vistas. The bank projectors of the seventeenth century, especially the English land-bank projectors and Law, who was one of them originally, had glimpses, varying in degree of distinctness, of the theory adumbrated above. But they fully realized the business potentialities of the discovery that money —and hence capital in the monetary sense of the term—can be manufactured or created. Their reputation, at the time and later, suffered greatly from the failure of their schemes—Law's schemes in particular—just as, in the nineteenth century, the reputation of fundamentally similar ideas suffered from association with wild-cat banking and with the failures of schemes that turned out badly without being fraudulent or nonsensical, such as the *Crédit Mobilier* of the brothers Pereire. But since there is a far cry from an economic principle to a banking project, these failures are not evidence in the court of theory.

Interpretation of John Law's theoretical position in matters of money and credit (on his theory of value, see above, sec. 2) presents difficulties quite apart from the fact that some of his arguments may have been no more than tactical moves. From the way in which he deduces the phenomenon of money—which, in the first instance, makes money a commodity—it seems that he must be classed as a theoretical metallist. This diagnosis derives support from his antagonism to debasement or devaluation—which he called an unjust tax, on the doubtful ground that it tends to hurt poor people more than the rich—and also from his practice, for he kept up redemption of his notes as long as he could. Since this seems to clash rather badly with the rest of his views, historians have brushed aside this evidence. But it is quite possible to arrive from the metallist principle at conclusions that seem to violate it, as the American example of our own time suffices to show. Law's argument admits of the following reconstruction: he first observed—a clear gain to analysis—that the use of a commodity as a means of circulation affects its value; from this it follows that the exchange value of the monetary commodity as money can no more be explained by its exchange value as a commodity than the latter can be explained by the former—although, of course, so long as the monetary commodity can freely move between its monetary and its industrial uses, the two must be equal; therefore he explained, quite logically, the exchange value of silver as money on the lines of the quantity argument (*abondance* of money as compared with *abondance des produits*); but since silver that serves as money has no other use than to buy goods, it might just as well be replaced by a cheaper material, in the limit[ing case] by one that has no commodity value at all, such as printed paper, for 'Money is not the Value *for* which Goods are exchanged, but the Value *by* which they are exchanged' [J. A. S.'s italics]. This, however, cuts the cable that so far [has tied money to a commodity having] 'intrinsic' value. Now he draws the conclusion that there is an advantage other than cheapness and absence of worry about how to get and keep [an adequate supply of money]—it is that the quantity of money is fully manageable.

[The preceding paragraph was unfinished with notes at the end which were filled in by Arthur W. Marget.]

This, then, seems to have been the work that gave birth to the idea of Managed Currency, which was subsequently lost to the large majority of economists until it forced itself upon them after 1919. The evident importance of the event makes it worth our while to stay for a moment to consider it. First, the relevant passages in Law's tract (*Money and Trade Considered* . . . 1705) acquire additional meaning by his practice, or rather by one aspect of it. We are not concerned with his particular schemes, from that of the *Banque Générale* (1716), which looks so innocuous and almost orthodox, to those of the *Compagnie des Indes* (1719), which look more and more visionary, and finally those of 1720, which were the ultimate resort of the strong swimmer in his agony. But one great plan was behind all this, in fact well advanced on the road to success: the plan of controlling, reforming, and leading on to new levels the whole of the national economy of France.[4] This is what makes Law's 'system' the genuine ancestor of the idea of managed currency, not only in the obvious sense of that term but in the deeper and wider sense in which it spells management of currency and credit as a means of managing the economic process. And this is what interprets and glorifies the modest passages of the tract.[5]

6. CAPITAL, SAVING, INVESTMENT

The word Capital had been part of legal and business terminology long before economists found employment for it. With the Roman jurists and their successors, it denoted the 'principal' of a loan as distinguished from interest and other accessory claims of the lender. In obvious relation with this, it later came to denote the sums of money or their equivalents brought by partners into a partnership or company, the sum total of a firm's assets, and the like. Thus the concept was essentially monetary, meaning either actual money, or claims to money, or some goods evaluated in money. Also, though not quite definite, its meaning was perfectly unequivocal, and there was no doubt about what was meant in every particular case. What a mass of confused, futile, and downright silly controversies it would have saved us, if economists had had the sense to stick to those monetary and accounting meanings of the term instead of trying to 'deepen' them! Before the eighteenth century, however, they hardly used it at all. Waiving such questions as whether or not St. Antonine of Florence evolved a capital theory, we merely note that in the seventeenth century terms like Wealth, Riches, Stock were often used where we should use Capital, and that throughout the eighteenth—and even in the first decades of the nineteenth—Stock was favored for use in the nascent capital theory.

---

[4] The failure was not due to this idea. . . [Footnote incomplete.]

[5] It is not suggested that Law had no forerunners. First, the idea of managed currency lurks in the reasoning of most of the bank projectors who preceded him. However, the case seems to be one of those in which it is right to link 'priority' with fullness and depth of comprehension. Secondly, in a sense every currency is always managed. Moreover, currencies had been tampered with for ages. But this is not what I mean . . . [breaks off, unfinished, at this point].

Stock, more or less in the sense of either durable or productive wealth—the latter exemplified by Child's stock of tools and materials—was, of course, the object of attention and of recommendations. But when I said that economists were late in finding employment for it, I meant employment in articulate analysis involving a 'theory' of the nature and functions of capital. Of this there were only rudiments before Cantillon and the physiocrats. It may surprise the reader to find Quesnay credited with laying the foundations of a capital theory, considering his emphasis on the role of natural agents. We must, however, go further than this and simply recognize the presence of one of those cases—they are as frequent in science as they are in politics—where a man achieves if not the opposite of, yet something quite different from, what he intends to achieve: the physiocrats were even responsible for one of the later theories of the productivity of capital. The whole process described by the *tableau* starts from given 'advances' and, moreover, runs on in terms of the annual advances. These advances are goods—to live on or to produce with—though their quantity may be expressed in terms of money, and they are precisely what capital means in one of the many senses of the word. This idea is so important for the general character of any theoretical scheme that adopts it that we may well form a group of all the schemes that do so and call it 'advance' economics.[1]

This point was almost immediately seized upon by Turgot, who sketched out the corresponding theory of capital. He emphasized—one may almost say, he 'rubbed in'—that wealth other than natural agents (*richesse mobilière amassée d'avance*) is a *préalable indispensable* for all production (*Réflexions*, LIII), which amounts to offering his shoulders for future attempts to treat capital in this sense as a factor of production. In his own way, A. Smith did the same thing. But one of the reasons for believing that he did not know the *Réflexions* (publ. in the *Éphémérides,* 1769-70) is that his exposition, though infinitely more prolix, falls far short of Turgot's. It looks to me as if Chapter 1 of Book II of the *Wealth* represents what he himself made of Quesnay's suggestion. The 'advance' idea is there and so is a hint of the productivity (necessity) of capital, but instead of a theory of interest, as in the case of Turgot (see below, sec. 7), only a 'taxonomy' of capital comes from it—Quesnay's primitive advances may have suggested the concept of 'fixed capital,' Quesnay's annual advances may have been transformed into 'circulating capital,' and A. Smith then proceeds to enumerate the various categories of goods that form the one and the other and to discuss what should and what should not be included in each category. It has often been pointed out that, owing to his different confusing points of view, this taxonomy is not quite satisfactory. We need not go into this. All that matters is that a physical or 'real' capital concept—which, however, included money, the 'acquired and useful abilities of all the inhabitants,' and also, though this is not obvious from Smith's catalogue, the means of subsistence of 'productive' laborers—was handed down to the theorists of the nineteenth century and, with but minor criticisms, accepted and further developed by most of them.

---

[1] The reader will observe, of course, that for a theoretical schema to qualify for inclusion in that group it is not sufficient to recognize the trivial facts that in order to produce, one must have tools and materials and that producing takes time—just as, in order to accept Newtonian physics it is not sufficient to recognize that, if severed from its branch, an apple will fall to the ground.

And so was the Turgot-Smith theory of saving and investment. With tremendous emphasis, A. Smith lays it down (ch. 3 of Book II) that 'parsimony, and not industry, is the immediate cause of the increase of capital'; that 'it puts into motion an additional quantity of industry'; that it does so 'immediately' (without lag) for 'what is annually saved is as regularly consumed as what is annually spent,' that is, the saver spends as promptly as the prodigal, only he does so for different purposes and the consuming is done by other people, that is, 'productive' laborers; and 'every frugal man is a public benefactor.' Turgot, only with a lighter touch, had written all this before.[2] But not Quesnay, nor Cantillon, nor Boisguillebert. Turgot evidently broke away from an anti-saving tradition established in his circle. Nor do I know of any earlier French economists—with the possible exception of Refuge—who could be credited with genuine 'predecessorship.' Among English economists only Hume had any claim. No doubt a host of writers, in the seventeenth century and before, declaimed against luxury (and the mischief of idleness), especially against imports of luxuries, called for or approved of sumptuary laws, and commended economy, at least for the bourgeois and the workman.[3] Among Spanish and English economists this was, in fact, quite a fashion. The latter in particular held that inadequate propensity to save was one of the reasons that made it so difficult for Englishmen to oust the Dutch—for whom they felt so much resentful admiration and who were supposed to be so frugal—from their leadership in international trade. But this linked up with a conception of saving and investment that stopped in most cases at the accumulation of stocks of durable goods, gold and silver in particular, and at a favorable balance of trade—the mercantilist angle to be considered in the next chapter. Nobody saw, or at any rate bothered about, the *modus operandi* of saving and capital formation per se. Turgot, then, must be held responsible for the first serious analysis of these matters, as A. Smith must (at the least) with having it inculcated into the minds of economists.

---

[2] In comparing the *Wealth* and the *Réflexions,* some doubt may assail us concerning the value of the indication previously mentioned about Smith's independence. For Turgot also says that, at least in the case of entrepreneurs, savings are converted into capital *sur-le-champ* (his italics). But Smith's 'immediately' certainly is the exact translation of *sur-le-champ.* And this is not unimportant; on the contrary, as will be seen in a moment, it is an essential feature of both theories and indeed their most serious shortcoming. That such a slip should occur independently in two texts is indeed quite possible; but it is not likely.

[3] To some extent, the confusing and confused mass of contradictory opinions on luxury may be straightened out, first by discarding, as not relevant to our subject, how-

Two points should be noted for future reference. First, in the face of frequent criticism, Turgot's theory proved almost unbelievably hardy. It is doubtful whether Alfred Marshall had advanced beyond it, certain that J. S. Mill had not. Böhm-Bawerk no doubt added a new branch to it, but substantially he subscribed to Turgot's propositions. Second, the theory was not only swallowed by the large majority of economists: it was swallowed hook, line, and sinker. As if Law—and others—had never existed, one economist after another kept on repeating that only (voluntary) saving was capital creating. And one economist after another failed to look askance at that word 'immediately.'

---

ever interesting from other standpoints, opinions that are (a) primarily morally motivated, in which case a writer may be 'against luxury' even if his economic argument leads him to attribute 'favorable' effects to it, (b) clearly traceable to bourgeois resentment against 'high living,' especially in the 'aristocratic' stratum; second, by distinguishing the different meanings that were attached to the word. During the eighteenth century, the plural Luxuries came more and more exclusively to denote nonnecessary commodities, the necessary ones including 'not only the commodities which are indispensably necessary for the support of life, but whatever the custom of the country renders it indecent for creditable people, even of the lowest order, to be without' (*Wealth of Nations*, Book v, ch. 2), so that luxury would be consumption exceeding what was later called the 'social minimum of existence.' Appraisal of opinion on the effects of luxury in this sense is complicated by two types of considerations extraneous to the fundamental problem: (a) so far as these luxuries were imported they come in for vituperation on balance of trade grounds (see below, next chapter); (b) so far as consumption of these luxuries presupposes relatively high wages, it was held by many writers, especially English ones, to be a handicap in the struggle for foreign markets, an argument that runs parallel to (a) and merges into the more general argument on wages that has been touched upon already. Apart from these two types of considerations, however, luxury in this sense was primarily viewed from the high-level consumption standpoint discussed in the text (above, sec. 1), even by later writers, who emphasized the role of saving, such as Hume, who added also the argument that industries producing luxury goods may prove a 'store of labor' for government to draw upon in emergencies. 'Vicious' luxury was commended by Mandeville as an important motive force and, though with qualification, by Hume. Typical for this line of thought was Butel-Dumont (*Théorie du luxe*, 1771). There is very little truth in the widespread belief that either A. Smith's own contemporaries or the economists of the seventeenth century needed his reminder that 'consumption is the sole end and pur-

But in effect—whatever else benevolent interpretation might make of it—this came to mean that every decision to save coincides with a corresponding decision to invest so that saving is transformed into (real) capital practically without hitch and as a matter of course or that, to put it differently, saving practically amounts to supplying (real) capital. The reader need not strain his imagination unduly in order to realize what a difference it would have made to doctrinal history if the possibility and, in depressive situations, likelihood of the occurrence of hitches had been pointed out from the first—of hitches that may paralyze the mechanism described by Turgot and cause saving to become a disturber of the economic process, hence possibly a destroyer instead of a creator of industrial apparatus. Not only would such an admission have broken off the spearhead from modern attacks upon the theory but it would also have made it a more effective analysis within the situations *for which it is quite true*. There was the less excuse for refusing to recognize the necessary

---

pose of all production' (Book IV, ch. 8). The reader should observe that, with Smith, this statement is no more than a platitude and entirely stripped of any connotation hostile to saving. But this meaning of luxury was not the only one.

Besides, there was a meaning in which luxury was associated with unproductive consumption. There were, from the middle of the seventeenth century on, several discussions on the latter, which, as we know, also greatly preoccupied A. Smith. The two elements that this meaning combines are exceedingly difficult to disentangle and space forbids us to enter into this—not very interesting—matter. Then there was the meaning in which luxury is the opposite to parsimony—luxury in this sense (Hume would have called it 'excessive' luxury) was bemoaned already by Thomas More, and this meaning, more or less distinct, runs through the whole literature on the subject; it was to be reasserted by Malthus. Again, there was the meaning that has perhaps more right than any other to be called the original one, viz. luxury as a style of life above one's station. The wish to protect distinctive class standards—spiced with the resentment of poor magnates against rich financiers—was an important factor in the policy that produced sumptuary laws (though there were others, such as the wish to compel people to reserve means for military uses). Since we shall not expect this point of view to play any great role in our literature, it is not uninteresting to note that some slight indication of it is to be found in the *Wealth of Nations*. Finally, there is the meaning that associates luxury with *ruinous* expenditure (dissaving). The wish to prevent people and in particular leading aristocratic and bourgeois families from ruining themselves was another important factor that made for the passing of sumptuary laws. In societies that center in a court and whose style of life derives its pattern from the 'magnificence' of the feudal household, fashion is much more compelling—for *all* except for the poorest classes—than it is in bourgeois society. And sumptuary laws, if effective, are perhaps the most obvious way of excusing the courtier or the leading officer of state from having to live beyond his means, and of preventing the rising merchant from setting a compelling example. This also explains why many Consultant Administrators who otherwise argued on the lines of Becher's principle, thought themselves in duty bound to frown upon luxury in this sense. From the large literature of the subject, it will suffice to mention: Juan Sempere y Guarinos (1754-1830) *Historia del luxo y de las leyes suntuarias de España* (1788). [J. A. S. was in doubt as to where to place this note on luxury. On the last page of the ms. of sec. 1 appeared the question: here * luxury?]

qualifications because they could have been taken from earlier as well as contemporaneous economists, especially from Quesnay's *Maximes*.

If saving is allotted such a part in the drama, the 'prince' (that is, public expenditure, hence public debts) cannot be expected to escape the role of the villain, or one of the villains, of the piece. The topic of public debts, though interesting from the standpoint of economic sociology and also from the standpoint of financial technique, is of little moment for us, because judgment and advocacy greatly prevailed over analysis. Therefore it will suffice to say that many authors tried hard to discover desired effects that might be attributed to public borrowing. Some indeed went so far as to make them a factor in national prosperity.[4] The opposite tendency prevailed, however—votaries of ideological interpretation are welcome to trace this to the increasing influence of the bourgeois mind, which in fact had more reasons than one to dislike cavalier finance. It was strongly sponsored by Hume and Smith. From their theory of saving—embryonic in Hume, developed in Smith—it follows indeed that public (or any) borrowing for nonproductive purposes spells setback in the growth of wealth. It is less easy to see why both should have been of the opinion that the public debts of their time were crushing burdens likely to produce bankruptcy and ruin. They hardly did more, however, than to express current opinion on the subject. The English public was in fact so nervous that the Pitt government in 1786 resumed, on a larger scale and more seriously, the policy of paying an annual sum into a Sinking Fund.[5]

7. INTEREST

The most significant development to notice in the interest theory of the period is the emergence, and all but universal acceptance, of the propositions (1) that interest on business loans is nothing but normal business profit transferred to lenders, and (2) that normal business profit itself is nothing but the return on the physical means of production, labor's means of subsistence included. So essential is it for us to grasp the full importance of this development which was to shape the subsequent history of interest theory that, in order to make it stand out clearly, we shall neglect side issues and cross currents as far as possible. In particular, we shall neglect discussions of interest on loans for purposes of consumption: for this . . . [incomplete].

---

[4] This was done, e.g., by Isaac de Pinto, *Traité de la circulation et du crédit*, 1771. But this line of thought had many adherents, especially in France.

[5] The plan adopted is usually attributed to the suggestion of Richard Price (1723-91; *An Appeal to the Public on the Subject of the National Debt*, 1772; *The State of the Public Debts and Finances in* 1783). The idea itself must be distinguished from the bold claim put forth by Price for his plan, according to which 'a State may, without difficulty, redeem all its debts by borrowing for this purpose,' which brought upon him much undeserved ridicule. Sir Nathaniel Gould (*An Essay on the Publick Debts* . . . 1726) had published similar views before. Both publications produced lively controversies into which we cannot—and need not—go.

[(a) *Influence of the Scholastic Doctors.*] We start again from the work of the scholastic doctors and their Protestant successors to which the reader had better refer before perusing this section. Their influence asserted itself in two ways. On the one hand, they provided one of the main topics of discussion: the controversy on the legality of charging and paying interest went on. In the second half of the eighteenth century, it flagged but it did not quite die out, and even Turgot wrestled, in his tract, *Mémoire sur les prêts d'argent*, with the Aristotelian position. Into this we need not go again. But a cognate point demands our attention. In most countries the moral issue was partly ousted by a purely economic issue, which turned not on the old question of principle, but on the question of the expediency of reducing the rate of interest by legislation. English merchants especially, looking with resentful admiration on commercial conditions in the Netherlands, embraced the theory that will naturally occur to the untutored practitioner, namely, that one of the causes, perhaps the main cause, of the flourishing state of Dutch trade in the seventeenth century was the low rate of interest that prevailed there, and they insisted that legal regulation could confer the same advantage upon England. It will suffice to mention Child as the most eminent among the many exponents of this theory and to glance in the footnote below at what seems to me to be the better part of the ensuing controversy from which the opposite theory, namely, that a low rate of interest is the consequence and not the cause of wealth, emerged victoriously—not to be seriously challenged again until our own time.[1] From this it does not follow, of course, that legal regulation of the rate of interest can have no sense at all. In fact, neither Locke nor A. Smith went so far as this. But in the end this view prevailed.[2]

On the other hand, scholastic doctrine also provided the theoretical (explanatory) ideas about interest from which the analysis of the seventeenth and eighteenth centuries started. Neglecting minor points, we shall concentrate upon these two: the monetary conception of interest and the proposition enshrined in Molina's pithy saying that 'money is the tool of the merchant's trade.' The scholastics did not indeed restrict the concept of interest to interest on loans of money, but the latter naturally commanded their attention more than anything else; they never agreed on or developed the idea that prospective profits are the source of the demand for business loans, but some of the most eminent of them adumbrated it with unmistakable clearness.

---

[1] Child may be said to have argued on the lines first worked out in a presentable manner in Sir Thomas Culpeper's *Tract against the High Rate of Usurie*, 1621 (enlarged ed., 1641). This tract, together with another not printed before, was reprinted and prefaced by his son, another Sir Thomas (1668). The latter also published in 1668 what is the classic treatment of this side of the controversy: *A Discourse shewing the many Advantages which will accrue to this Kingdom by the Abatement of Usury together with the Absolute Necessity of Reducing Interest of Money to the lowest Rate it bears in other Countreys.* The opposite view is well stated in a pamphlet entitled, *Interest of Money Mistaken, Or, a Treatise, proving that the Abatement of Interest is the Effect and not the Cause of the Riches of a Nation* that appeared in the same year and in Thomas Manley's *Usury at Six per Cent Examined* . . . (1669). To this Culpeper junior replied with *The Necessity of Abating Usury Re-asserted* . . . (1670). Petty, North, Locke, and Pollexfen, with varying degrees of emphasis, are the principal names associated with the victory over the Culpeper-Child position.

[2] The first economist of real authority who held that view was Petty. The next to go even further was Turgot. The one to make it prevail definitively, Bentham. But it was held also by Justi, at least in principle.

During the seventeenth century and far into the eighteenth, the large majority of economists looked upon interest—as many of us do again now—as a monetary phenomenon. In particular, this is true of the Culpepers, Manley, Child, Petty, Locke, and Pollexfen, not to mention any continental writers. In the case of Petty, direct scholastic influence is not inconceivable, since he had received part of his education at a Jesuit college. Looking, quite in the spirit of the scholastic fathers, for a special reason independent of, and additional to, the mere act of transferring money to the borrower, that would explain a premium, he hit upon, or rather resuscitated, the 'inconvenience' (a *damnum*) suffered by the lender who bound himself not to call for his money during a stated time. In any case—and in spite of the fact that he related this inconvenience to the rent of so much land as the same sum would buy—it is always money he is thinking of, and it is the quantity of money which is held to determine the rate of interest without there being any indication of the ceteris-paribus provisoes that would be required in order to make this true. Locke goes somewhat deeper than this. Owing to his clumsy way of expressing himself, it is extremely difficult to do him justice, but if I have caught his meaning, he may be credited with having introduced explicitly and having developed the second of the two ideas mentioned above. Again interest is a price for *money* lent. But the 'supply' on the money market must be seen in relation to the debt situation and the state of trade—high profits raising, low profits reducing, the rate. Though we cannot stay to prove it, still less to consider objections, I think that, at a push, this may be interpreted as an embryonic form of what is now known as the Swedish loanable-funds theory: interest is explained and determined by a demand proceeding from expected profits and meeting a supply of 'loanable funds.'

[(b) *Barbon: 'Interest is the Rent of Stock.'*] But further development did not take this line. There is no bridge between Locke and the monetary interest theories of today. Instead, there was a new departure, which was to be so successful that even now we find it difficult to be as surprised at it as we ought to be. There are, so far as I know, only the most elusive indications of it before 1690, when Barbon (*Discourse of Trade*) wrote the momentous statement: 'Interest is commonly reckoned for Money . . . but this is a mistake; for the Interest is paid for Stock,' it is 'the Rent of Stock, and is the same as the Rent of Land; the First is the Rent of the Wrought or Artificial Stock; the Latter, of the Unwrought or Natural Stock.' [3] If the reader is to understand the history of interest theory during the nineteenth century, and some part of it even during the first four decades of the twentieth, it is absolutely necessary to realize fully what this means.

---

[3] Locke, also, compared interest to rent but in a quite different sense, which adds nothing to the monetary view of interest and is without deeper meaning: the lender of money, according to him, receives interest as the landlord receives rent.

At first sight, Barbon's statement might well sound trivial: of course, the borrower does not normally want the money in order to look at it; what he really wants, if we neglect the purpose of refinancing other obligations, are the goods and services that he actually buys with it. Neither do we want, for its own sake, the knife with which to cut our food, and yet it does not follow that the price we pay for the knife is 'really' paid for the food. For certain purposes we may indeed, for instance by means of the theory of imputation (discussed below, Part IV) adopt such a view of the matter. But it would be a most astounding as well as important result if it were permissible to adopt it for all purposes. Granting even that business loans are normally used for purchasing or hiring real capital in the sense of producers' goods and services, it does not follow that the interest paid for the former is 'really' an element of the price of the latter: interest may bear a particular relation to 'money' as distinct from the goods that are bought with it, or it may be a price for something else—the sacrifice involved in saving, for instance—that cannot be simply *identified* with 'real capital.' To aver that it is possible to brush aside the monetary element without losing anything essential in the process is therefore an extremely bold step—which neither the scholastics nor Petty nor Locke thought of taking, though the triviality above cannot have been unknown to them; in particular, it was the decisive step toward the 'real' analysis of the nineteenth century, according to which money was just a 'veil' that it was the business of analysis to lift, which is precisely the center of the analytic difficulties created by Real Analysis.

In addition to the service or disservice that Barbon rendered by the impulse he gave in the direction of Real Analysis, there is another aspect to his performance that is hardly less important. If interest is the return on 'wrought stock'—produced means of production—exactly as rent is the return on 'unwrought stock'—natural agents of production—then it is goods of some kind or other that the lender 'really' possesses. As a matter of fact, it is the manufacturer or trader who possesses such goods, and he gets them either by producing them himself or by buying them from other producers and not from the capitalist or lender. To neglect this and to reason as if the latter lent goods is another stroke of analysis, the boldness of which is hidden to us only by our familiarity with it. But then the return on these goods materializes in the hands of the businessman who uses them and constitutes the main—and theoretically basic—part of his profit, at least if we choose to make light of his 'trouble and risk.' Thus we easily slip into a position that may be characterized by the equivalent propositions that the business firm earns interest or that the lender receives profit—not, as would seem more natural to the unprejudiced mind, an income sui generis of which profit is merely the most important source.

[(c) *Shift of Analytic Task from Interest to Profit.*] For the whole of the nineteenth century and beyond, this shifted the analytic task from interest to profit. With the partial exception of abstinence and psychological-discount theories, the phenomenon to be explained was the net surplus of business, which, in turn, was essentially a surplus arising from the use of an assemblage of certain physical goods; that this surplus, cleared of accessories such as compensation for trouble and risk, had to be handed to some other person, if this person and not the business manager was its real (though not legal) owner, hardly required independent explanation. This applies also to Böhm-Bawerk and Wicksell, though the latter made the first step beyond this theory and must even now be kept in mind when we compare such a theory as Keynes's with other interest theories: the object of analytic endeavor is different.

It is not too much to say that this was to be the dominant feature of the theorist's general picture and even of economic sociology for everyone: the businessman became the 'capitalist.' Fundamentally his income was income from ownership of goods, an impersonal return.

[The two preceding paragraphs were on a single page with notes (both shorthand and longhand) to indicate how the argument was to be continued. This section on interest was more fragmentary than any other part of this unfinished chapter. It was obviously an outline that would have been filled in and completed, had the author lived.]

A. Smith substantially accepted this theory of interest and of the capitalist process. The nineteenth century in turn accepted it from him. However, before considering the precise form which he gave it, we must glance briefly at its development between 1690 and 1776.

Barbon's *Discourse*, on this point at all events, did not meet with success. The tract seems indeed to have been forgotten very soon. Thus, Barbon's fundamental idea remained in abeyance until 1750, when it was again expounded —for all we know, independently rediscovered—by Massie,[4] whose analysis not only went further than Barbon's but also gathered force from its criticism of the views of Petty and Locke. Two years later, in his volume entitled *Political Discourses*, Hume published two essays ('Of Interest' and 'Of Money') that do not seem to have received due tribute from recent historians. It is indeed true that, on the surface, we see little more than synthesis and effective re-exposition of ideas that had been put forth before. This impression is particularly strong with authors who attend primarily to certain practical results he drew from his analytic set-up, such as that interest is not simply a function of the quantity of money, that low interest is a consequence and not a cause of wealth, that it cannot be determined by legislation, that it is correlated with profits in a relation of mutual interaction, and that it is a 'barometer of the state,' low interest being 'an almost infallible sign of prosperity' (which, of course, is not true in every sense of 'prosperity')—none of which were novel. But the analytic set-up with which Hume backed all this, though sketchy, can be called synthetic only in the sense in which synthesis may transcend coordination and be creative. It amounts to accepting Locke's explanation of the demand for loans—definitely *loans* this time, not 'money'—by the needs of spendthrift landowners and by the profit expectations of businessmen, and to replacing Locke's supply of money by the supply of savings. This allows for the close relation between profit and interest without identifying them, and admits the monetary aspect—particularly as regards short-run effects of variations in the quantity of money on the rate of interest that were also recognized by Ricardo—without making it dominant. In short, we have here a schema that need only have been worked out in order to produce a much better and more complete theory of the interest phenomenon than can be found in either Ricardo or Mill. But precisely the most valuable points were lost.

---

[4] Joseph Massie, *Essay on the Governing Causes of the Natural Rate of Interest* (1750).

[(d) *Turgot's Great Performance.*] Turgot's[5] contribution is not only by far the greatest performance in the field of interest theory the eighteenth century produced but it clearly foreshadowed much of the best thought of the last decades of the nineteenth. Like Hume, Turgot argued that the quantity of money does not determine the rate of interest, very nicely emphasizing the conceptual independence of the two meanings of the phrase 'value of money' —its value in the money market and its value in the markets of commodities— and even going so far as to assert that an increase in the quantity of money that raises commodity prices might conceivably *increase* the rate of interest. Also like Hume, he substituted supply of savings for supply of money. And there are other points that Hume made before him. But his theory goes much deeper than all that and is quite different in content as well as in background.

---

[5] As in the case of Hume, critical analysis does not seem to have done full justice to the essential point in Turgot's performance. This applies in particular to by far the most eminent of his critics, Böhm Bawerk (*Capital and Interest*, Book I, pp. 61-9 of English trans. of 1932), who pinned him down to a 'fructification theory' of interest, an interpretation that does not do justice even to the letter, let alone the spirit, of Turgot's treatment. Cassel's analysis (*Nature and Necessity of Interest*, 1903) is much more satisfactory. This 'fructification theory' was, in fact, quite frequently used in the eighteenth century and even before in order to counter the Aristotelian argument about the sterility of money: since it is possible to use money for the purchase of land, which does yield a net return, therefore money will yield—most authors would have said: therefore it is 'just' that money should yield—a net return, whatever the purpose for which it is lent. Hutcheson argued like this, and Petty might perhaps be accused of having done so. It is obvious that this reasoning, as an *explanation* of interest, is, or at least may be, circular, because the value of land itself depends upon the rate of interest. But Turgot, though he stated the equilibrium proposition that a sum of money will be equivalent in value to a piece of land that produces the same net revenue (*Réflexions*, LIX), was so far from treating this fact as a datum from which to start, in explaining interest, that he made an elaborate attempt to determine the exchange ratio between land and *richesses mobilières* (LIII et seq.) and to deduce from it the value of lands in terms of money.

[The reader's attention is called to the fact that the numbering of the sections of the *Réflexions* in the *Oeuvres* edited by G. Schelle (1913-23) differs from the original numbering in the *Éphémérides*. For example, XXI, XXII, and XXIII became XXI in the Schelle edition and LXXIII in Schelle had been entirely suppressed in the *Éphémérides*. Apparently J. A. S. used the original numbering in the *Éphémérides* (1769-70), which is also the numbering used by Dupont de Nemours in vol. V of his edition of the *Oeuvres de Mr. Turgot* (1808-11).]

Canonist influence, as we might expect, is much in evidence—though, of course, scholastic ideas are sometimes made to serve exactly opposite practical conclusions—and one essential feature of Turgot's scheme, the identification of capital with 'advances,' goes back to Quesnay or Cantillon. The *hommes industrieux* share their profit with capitalists who supply the funds (*Réflexions*, LXXI). The share that goes to the latter is determined like all other prices (LXXV) by the play of supply and demand among borrowers and lenders (LXXVI), so that the analysis is from the outset firmly planted in the general theory of prices. At first blush and on the surface, interest is the price paid for the use of money (LXXII, LXXIV). But why does the use of money command a price or, to put it differently, why does the mechanism of supply and demand work out in such a way as to produce normally a premium on present as compared with future money? Turgot realized that it is not enough to answer that money lent is money saved. His answer was that the *fonds* supplied by the capitalist represent *richesse mobilière* or advances, which are an indispensable prerequisite of production (LIII): capital yields interest because it bridges the temporal gap between the productive effort and the product (LIX, LX). By now, this idea has become as stale as a quotation from Hamlet. Moreover, many of us have ceased to believe in its explanatory value. For both reasons, the reader may find it difficult to admire as he should the brilliance of the stroke by which Turgot, exploiting Cantillon's or Quesnay's conception of capital, tied the phenomenon of interest to a most elementary fact about production. The propositions that the rate of interest is the *thermomètre* of the (relative) abundance or rarity of (real) capital (LXXXVIII)—in other words, that the rate of interest is negatively correlated with the rate of saving—and that it measures the extent to which production can be carried (LXXXIX) also acquire additional meaning in the light of this theory. The first remained practically unchallenged until our own time, the second stands unchallenged even now.

As has been stated before, A. Smith stereotyped the doctrinal situation. But in doing so he dropped precisely the most promising suggestions proffered by Hume and (if he knew the *Réflexions*) by Turgot—still more those that he might have found in Locke—so that his successors started from a formulation that was much more Barbonian than that of any of these writers. In the *Wealth*, the monetary aspect of the interest problem is definitely reduced to a matter of form or technique. 'What the lender really supplies . . . is not the money but . . . the goods which it can purchase' (Book II, ch. 4), and there is *nothing* in the views of 'Mr. Locke, Mr. Law, and Mr. Montesquieu' that an increase in the quantity of gold and silver lowers the rate of interest (*ibid.*). The tendency of interest to fall he explained in exactly the same way as the tendency of profit to fall (Book I, ch. 9, which really deals with the same topics as Book II, ch. 4), both of which A. Smith seems to accept—with a qualification about 'acquisition of new territory or of new branches of trade'—as unquestionable facts. And this is quite logical for, as should be clear by now, they are, in A. Smith's schema, really one and the same thing. A. Smith does distinguish them: profit also includes compensation for 'trouble' and 'risk,' whereas the lender receives his interest without such trouble and risk. But these are relegated to a secondary position. Essentially, profit is 'profit of stock,' and interest which goes to the capitalist employer is received for 'stock' (goods) lent. Whether the stock be his own or borrowed from some other person, to supply the workmen with stock is the businessman's basic function. First and foremost, he is the 'capitalist' and *as* capitalist he is the typical employer of labor, whose basic function it is to supply this stock to the workmen though that capitalist employer need not always do the employing himself, in which case . . .

[This paragraph was written on a yellow sheet still adhering to a pad and was obviously unfinished. The page, which was crowded with notes in Austrian shorthand and in English longhand, is reproduced in the Appendix.]

CHAPTER 7

The 'Mercantilist' Literature[1]

[1. INTERPRETATION OF THE 'MERCANTILIST' LITERATURE] 335
[2. EXPORT MONOPOLISM] 338
[3. EXCHANGE CONTROL] 340
[4. THE BALANCE OF TRADE] 345
  [(a) *The Practical Argument: Power Politics*] 346
  [(b) *The Analytic Contribution*] 347
  [(c) *The Balance-of-Trade Concept as an Analytic Tool*] 352
  [(d) *Serra, Malynes, Misselden, Mun*] 353
  [(e) *Three Erroneous Propositions*] 359

  [(a) *Concept of the Automatic Mechanism*] 365
  [(b) *Foundations of a General Theory of International Trade*] 367
  [(c) *General Tendency toward Freer Trade*] 370
  [(d) *Benefits from Territorial Division of Labor*] 373

QUESTIONS OF INTERNATIONAL economic relations loomed so large on the horizons of all the authors of this epoch that we have already had to refer more than once to their propositions about these problems. It is nevertheless necessary to return to the charge and to examine some of these propositions more closely in order to introduce another batch of writings and to extract from them what contributions to analytic economics they may contain. I shall group those propositions under the headings of Export Monopolism, Exchange Control, and Balance of Trade. Doctrines concerning the second and third, particularly the third, are usually considered the core of that imaginary organon, the 'mercantilist system' of traditional teaching. To many economists, they mean in fact the whole of it. This tradition was established by Adam Smith, whose famous attack upon what he called (following, perhaps, the lead of the physiocrats) the Commercial or Mercantile System (*Wealth*, Fourth Book) centered in an argument about the balance of trade, although he was not blind to other aspects.

[1. INTERPRETATION OF THE 'MERCANTILIST' LITERATURE]

The reader presumably knows that these specifically 'mercantilist' doctrines have given rise to a controversy among historians of thought on which it is worth while to comment before embarking upon our task. This will not only clarify the issues involved but also afford an interesting illustration of the principles of interpretation outlined in Part 1.

---

[1] [This chapter, though completed and typed at an early date (June 1943), had only a tentative title and no section titles. In reporting on the progress of the *History* in 1946 or 1947, J. A. S. told me that this chapter could be published substantially as it stood but that a good deal of work remained to be done on other chapters in Part II.]

The opinions the 'mercantilist' writers held about those topics—so far as they can be said to have held uniform opinions at all[2]—came to be looked upon not only with disapproval but also with contempt by the large majority of the economists of the nineteenth century. They could see nothing but error in them and, in dealing with their predecessors, developed a practice according to which it was all but sufficient for putting a work out of court to attach to it the slightest tinge of 'mercantilism.' This can be verified, in an almost amusing way, by consulting the relevant articles in *Palgrave's Dictionary of Political Economy*.[3] Next, an opposition to this free-trade view arose; voiced mainly though not exclusively by German writers, it went practically to the other extreme. This opposition also succeeded in establishing a tradition, though a less general one, which of late seems to have elicited a reaction that, joining forces with the surviving elements of the 'liberal' tradition, in turn bids fair to overshoot the mark. Professor Jacob Viner's monograph may perhaps be cited as an instance.[4]

Now the first thing to observe about this prolonged campaign is that both the antimercantilists and the promercantilists were primarily interested in mercantilist *practice* and that the opinions of both hence were and are primarily a matter of political preference. The English critics were out of sympathy with what had been *done* in the mercantilist age. The German sympathizers were not in favor of all the aspects of mercantilist practice, but they were in favor of some measure of national autarky, of state management, and above all of state building. All this is completely irrelevant to our purpose, and the only thing that needs to be said about it is this: Both critics and sympathizers were victims of the belief, so dear to that rationalist epoch, that their opinions about policy were scientific inferences from premises that had been laid down in a scientific spirit. Especially the English utilitarians, such as John Stuart Mill, looked upon their recommendations concerning policy as an engineer would look upon his recommendation about the construction of an engine. Their present was invariably 'this enlightened age.' Hence practical and theoretical 'error' was for them equally definite and indeed the same thing.

---

[2] This is in fact the first issue involved.

[3] Let us notice, in passing, that for the same reasons exactly the same thing is happening now to the economists of the liberal epoch.

[4] Jacob Viner, 'English Theories of Foreign Trade before Adam Smith,' republished, in revised form, as chs. 1 and 2 of his *Studies in the Theory of International Trade* (1937). I wish to acknowledge my indebtedness to this excellent piece of work. In perusing it I have sometimes wondered, however, whether Professor Viner is prepared to pass the same peremptory judgments on certain measures and arguments of our own time that are exactly similar to those of the mercantilist age. Another book that must be mentioned here is *The Theory of International Prices* by James W. Angell (1926; chs. 2 and 8). See also Viner's review of this book in *The Journal of Political Economy*, October 1926.

This standpoint, which partly accounts for their pontifical attitude, is of course wholly untenable as we need not stay to prove once more.

Second, the promercantilists held what the antimercantilists by implication denied, namely that mercantilist policies were not only understandable in the sense in which everything is, crime and folly included, but also in the much more significant sense that, taking account of the circumstances and opportunities of the times, they constituted adequate means for securing what with the same proviso were rationally defensible ends. Here, as previous argument suffices to show, the promercantilists score, though not to the extent they themselves believed.[5] At all events, this must be admitted by all those who are not willing to condemn modern commercial policies of a similar type, which in fact enjoy the support of many who know all about their Smith, their Ricardo, and their Marshall. For the sake of future reference, let us call this the Practical Argument.[6]

---

[5] In the thicket of 'mercantilist' measures it is easy to find many that did not serve the ends their promoters had in view or that produced other effects besides those that were desired, which would have prevented their being taken if they had been foreseen. Adam Smith's common sense revelled in instances of this (Book IV, ch. 8), which might easily be multiplied. It is however possible to separate off 'mistakes' and to carry the discussion up to a plane of principle on which they may be assumed away, though it must not be forgotten that any system of management is prone to produce a goodly crop of them. This in fact would have been Smith's defense if somebody had accused him of unfairly using 'mistakes' in a discussion of 'principles.'

[6] At this point, a sideline branches off which we see immediately if we reflect that both the ends to be served by a policy and the means to be considered rational, in other words, the questions concerning the wisdom or unwisdom of a policy, are relative to schemes of value that are themselves relative not only to the national situation, but also to the kind of men who face it and thus, among other things, to the class structure and to group interests. The statement in the text that, to some extent, mercantilist policies admit of rational defense (which, mind, never amounts to 'justification' in any absolute sense) must be understood to imply this. Many policies of the mercantilist age may in fact be traced to the interests of, or to the pressure exerted by, groups that can be definitely identified and from whose standpoints they may acquire a character of rationality that would otherwise be lacking. Adam Smith had an eye for this as he showed in Book IV, ch. 8. I will emphasize again that this has nothing to do with the truth or value of any given proposition or line of reasoning. The most stubborn class interest may induce true and valuable analysis, the most disinterested motive may lead to nothing but error and triviality. I hope I have made this quite clear in Part I. Also, I want to repeat that considerations of the class now envisaged do not per se entitle us to attribute conscious or even subconscious interested motive to any *individual*. Apart from the fact just mentioned, viz. that motive has nothing to do with the objective nature of a proposition, it is unsafe to talk about individuals' motives. The only mind accessible to us is our own. In talking about motives of individuals we may be revealing nothing but our own propensities. Wheeler was secretary to the Merchants Adventurers. Mun and Child were connected with the East India Company. Milles was a disgruntled bureaucrat. Perhaps none of them has a claim to be included among the Consultant Administrators. But little more than triviality results from stressing this.

But, third, this does not prove anything for the analysis, the results of which have been used in order to defend those policies. A man may do what, from his standpoint and in his circumstances, is for him the right thing and yet do it for reasons that are complete nonsense.[7] The promercantilists, in particular the German ones who cared little and knew less about economic theory, were therefore wrong in thinking that they had proved anything for what they conceived to be mercantilist doctrine when they had succeeded in making out, in the sense defined above, a partial case for mercantilist practice. Moreover, it should be borne in mind that it is not enough to show that a proposition we find in a mercantilist pamphlet makes sense *to us*, that is to say, that *we* can prove it to be correct. For many modern propositions bear a striking surface resemblance—let us hope that the resemblance does not go below the surface—to quite primitive ones which can be easily disproved. To read our meaning uncritically into old texts amounts to betrayal of the historian's duty as much as does overemphasis on every mistake in formulation. This class of considerations we shall, for purposes of reference, call the Theoretical Argument. Armed with these distinctions we now proceed with our task.

[2. EXPORT MONOPOLISM]

To begin with, the practical argument is strongly in favor of those writers of that age who held that monopoly and quasi-monopolistic co-operation, no matter what their effects may have been on domestic industry and trade, filled an essential function in foreign commerce. This is what I mean by export monopolism. At all times people have judged differently monopolistic practice that was directed against foreigners. Thus, the American Congress, otherwise so hostile to anything that may be made to look like monopoly, was easily persuaded to relax antimonopolist legislation for the benefit of export trade by the Webb-Pomerene Act. The proposition involved is as simple as it is—so far as it goes and if only immediate effects are considered—correct: monopoly gains from foreign trade are net gains to a nation because the items that would have to be subtracted if these gains were made in the domestic market are equated to zero. Moreover, until the middle of the eighteenth century and in many parts of the world until much later, trading was only possible within protective *ad hoc* arrangements that the traders had largely to provide themselves. This did not necessarily involve monopolistic action. But it spelled organization and co-operation that could easily extend to price and general business policy, not only to facilitate exploitation but also to regulate it and to defend standard practice against substandard connationals. Of this, the Society of Merchants Adventurers affords a telling example.[1] Finally, it seems too obvious to require explicit statement but is surprisingly often left out of account by critics of 'mercantilist theories' that that age was the age of buccaneering imperialism and that trade was associated with colonization, with uninhibited exploitation of the colonies founded,[2] with private warfare for which the governments, especially the English, frequently declined responsibility, and with conditions permanently verging on war. The classic example of all this is the East Indian; the only modern instance, the Rhodesian case. This explains many things perfectly rationally that were bound to vanish under the influence of different conditions, even if there had not been any progress at all in the grasp of the logic of economic phenomena: in fact this progresss presumably had very little to do with the change in practice.

---

[7] The reverse is also true—particularly in economics—in the sense that it is possible to reason correctly on a model constructed in an unexceptionable way and yet to arrive at wrong diagnoses concerning a reality that fails to conform to the model. We shall encounter instances of this. To top it all, scientifically interesting theories may be associated with quite uninteresting practice, interesting practice with uninteresting theories.

The two main sources of the large stream of literature on the subject of export monopolism—including colonization—flowed from the one fact that the policies of the great companies affected domestic interests also, and from the other fact that their success aroused the envious hatred of both the squire and the common man against the 'nabobs.' Attacks elicited replies, of which it may be worth while to notice the best example that has come to my notice: John Wheeler's defense of the Merchants Adventurers—among other things against the bureaucratic spokesmen for regulation who know nothing about business (*tout comme chez nous*). This work mentioned before in Chapters 3 and 6, entitled *A Treatise of Commerce. Wherein are shewed the Commodities arising by a well ordered and ruled Trade, such as that of the Societie of Merchants Adventurers is proved to be: Written principally for the better Information of those who doubt of the Necessarinesse of the said Societie in the State of the Realme of England* (1601), was also written, as we may add, with impending hostile legislation in view. In my opinion Mr. Wheeler did extremely well, and his argument successfully disposes of some of the points that are invariably raised in discussions about monopoly. His economics is not a bit below the level that we observe in similar popular or political or forensic arguments today. But he contributes nothing to our collection of scientific tools. His analytic economics was, on the whole, not wrong. There was very little of it, however. Because of its prominence, the East India Company attracted the lion's share of public attention and hostility. This accounts for a large part of the literature in question. So far as I can see, however, there is nothing in it to interest us except the arguments and counter-arguments about the company's exportation of monetary metal and about the competition which—though harassed by legislation and administration—it offered to English woolens by its imports of Indian wares. However, these arguments and counter-arguments enter into the general discussion concerning the balance of trade (see sec. 4). Attention is invited to the footnote below.[3]

---

[1] It is hardly possible to understand the circumstances that conditioned the economic thought of that period and in particular to appreciate the points made—and to be made—in the text without a pretty extensive command of the relevant chapters of economic history. Let me therefore again recommend a study of Professor Eli F. Heckscher's volumes: *Mercantilism* (first publ. in Swedish, 1931; German ed., 1932; English trans. by Mendel Shapiro, 2 vols., 1935).

[2] The lack of inhibition displayed by Spaniards, Frenchmen, and Englishmen alike is a very important element of the case. The economic reasoning about colonies runs on completely different lines and may, without involving contradiction, lead to completely different results according to the practice visualized by different men. Warren Hastings' practice—to wit: shameless robbery—is one thing. William Bentinck's practice—to wit: benevolent administration—is another thing. And the economic advantages differ accordingly. A rough dividing line can be discerned by studying the evolution of the attitude toward the slave trade.

[3. EXCHANGE CONTROL]

Next let us see how the practical argument stands in the matter of Exchange Control. War, as we know from experience, inevitably induces government control of economic life and, not less inevitably, creates bureaucracies to administer it which then not merely cling to their powers but automatically strive to expand them. Imports, exports, and foreign exchanges are obviously among the most important of the things to be controlled. The argument for control also applies to conditions permanently verging on war. Moreover we must take into account the spirit induced by war and the incessant threat of war, the frame of mind in which injury to a foreign nation is almost as welcome as gain to one's own, or, to put it differently, in which the policy of international economic relations merges with a policy of economic warfare and becomes just one of the weapons in the perennial game of power politics. If it be conceded that all this holds true for that epoch, the rationale for its practice in the matter of foreign exchange should be obvious, especially if we do not lose sight of the expansive tendency inherent in all bureaucratic practice. Embargoes on coined and uncoined gold and silver we simply subsume as a necessary complement under exchange control, although in more primitive cases they were the main measure to be taken or even all that it was possible to do.[1]

---

[3] Monopolistic policies were related to, though of course not congruent with, the Staple (*jus emporii*), which will be touched upon in connection with the two other topics we have singled out for discussion. But it is convenient to make its acquaintance right now. For our purposes we must carefully distinguish three different aspects of it. First, corporatively organized *traders* sometimes hit upon the device of making certain towns centers or entrepots of their trade in order the better to regulate it. The Merchants Adventurers may again serve as an example. John Wheeler in fact argued the advantages of 'mart towns.' Second, the towns themselves, which were in a position to do so or to prevail on their territorial governments to help them to such a position, tried to exercise staple rights, that is to say, to force traders to pass through them, to offer their wares for sale, and to submit to other restrictions that were, or were thought to be, profitable to those *towns*: here the foreign traders did not engineer the staple, but were the victims of it, sometimes in ways that to us look like the acme of irrationality and vexation. This is the type that is usually associated with the term Staple. It spread in the thirteenth century and after—all over Italy (Genoa and Venice being the most powerful centers of it) and then over the rest of Europe, including Russia. It also spread to England, as Edward III's Ordinance of the Staple shows. Professor Heckscher's statement to the contrary is not quite understandable to me. From this arose, third, the practice of forcing international trade into prescribed channels for the real or putative benefit of a *country* as a whole and for the purpose of injuring the foreigner. It is this type that was mainly discussed in the English literature. England—improving on the Spanish example—in fact developed it beyond all precedent. Her participation in the staple policy of the second variety practically ceased, of course, with the loss of Calais in 1558, whereas, e.g. in Venice, it continued to exist until Napoleon's conquest of that city. But her staple policy of the third type was then in its beginning and a whole century had still to elapse before its legislative bases were completed by the Navigation Act of 1660 and the Staple Act of 1663. The statement one meets so often, to the effect that, so far as England is concerned, the staple system died in 1558, is therefore misleading and a serious bar to the understanding of a considerable part of the mercantilist literature. Of course, the system gradually shaded off into ordinary protectionism in the modern sense, but this does not justify us in overlooking its peculiar features that were so important a part of the politico-economic scene of those times.

It may be useful, however, to present that rationale in a more general form, that is, without reference to the particular conditions of war economy. In doing so I shall consider perfect exchange control only, that is, the case in which a public authority, holding an effective monopoly of exchange transactions, can requisition and allocate foreign exchange as it pleases. Then, this authority can (a) tide over temporary shortages of foreign exchange which, if not attended to, may produce disproportionate consequences, especially through cumulative processes; (b) facilitate the orderly discharging of debts in situations in which automatic adjustment is impossible owing to inhibitions in the functioning of the international market; (c) prevent or defeat bearish speculation in an exchange market that lacks its normal resilience; (d) prevent undesired (depressive) effects of automatic adjustment that may ensue even where such automatic adjustment is possible; (e) prevent certain imports or exports and encourage others and thus powerfully influence national production; (f) improve a country's terms of trade within limits, which may be widened by complementary restrictions, by introducing a monopoly element into its transactions with foreign merchants.

---

[1] The practice of exchange control, as well as the discussion about it, was at the highest level in England. But the former reached its culmination much before the latter, viz. in the reign of Elizabeth in which, under the influence of a persistently favorable course of events, the decline set in also. It then consisted of a control over transactions in foreign exchange, administered by a special public officer, the Royall Exchanger, and was supplemented by an embargo (lifted definitively, after various ups and downs, in 1663 for everything except English coins) and by the Statute of Employment, 1390, which, a member of quite a family of similar measures enacted in many countries, attempted to enforce importers to employ the proceeds of their sales in purchasing English goods. After the First World War there were instances of similar measures in several European countries, e.g., Austria. The Royall Exchanger of course has found plenty of successors in present-day Europe whose practices no doubt differ from his in technique but do not differ at all in principle.

Two points remain to be added. First, in order to prove itself the sharp weapon it is capable of being, exchange control not only requires attention to the net result of all the transactions that cross a country's frontier or to the net results of a country's transactions with every other country taken separately—the bilateral trade principle of today—but it also requires attention to the transactions in every individual commodity and of every individual trader. This is particularly necessary if full advantage of the discriminatory possibilities of the method is to be reaped. Second, in order to be fully effective as a tool of comprehensive planning, exchange control (plus embargoes on monetary metals) must be implemented by other controls that act directly on the individual transactions themselves. Many such controls have been used at various times but that epoch had a *specificum* of its own, the institution of the Staple.[2] It is obviously much easier to control exchanges when trade is already controlled by being forced into prescribed channels; and the staple towns with their apparatus of mints, comptrollers, and hostelers (practically jailers of foreign merchants) offered unrivaled administrative opportunities for controlling the exchange market. It should be borne in mind, however, that the two policies while primarily complementary were also to some extent capable of being substituted for one another.[3]

Now, whatever we may think of the more remote effects of any such policy, especially if practiced by all countries, and whatever we may think of the way in which it was actually worked—legislation was (and is), of course, at all times a highly irrational heap of contradictory measures—it was not simply nonsense in principle and no writer who advocated it under the conditions of that time can be accused of having stood for nonsense. This certainly holds so far as the practical argument is concerned and hence for the practitioners, among whom Sir Thomas Gresham (1519-79) stands out without a peer.[4] John

---

[2] See footnote 3.

[3] There is thus nothing astonishing, and especially no contradiction, in the fact that some writers advocated both the staple system *and* exchange control and others exchange control instead of the staple system. Let us note in this connection that, roughly up to 1600, Free Trade as a program meant developing the staple system and fettering or even breaking up the merchants' companies. After 1600 it meant forcing the doors of those companies so as to make it possible for every trader to enter them. In both cases free trade meant a sort of 'trust busting.'

[4] He was a type that can no doubt be found everywhere but of which the English specimens are to this day so much more frequent and so much superior that it may well be called English: the businessman who is just as much a public servant as he is businessman and who, though perfectly successful in looking after his own advantage, serves the state in ways that are beyond the competence of the mere public servant. As a businessman he was a mercer, banker, entrepreneur (paper milling), and public benefactor. As a public servant he was first 'factor' (fiscal agent) for the English crown in the Netherlands—keeping up its credit, managing the course of the English exchange, negotiating loans, acting as buyer of war materials, getting hold, by hook or by crook, of bullion to ship to England, and so on—and then, at home, exchange dictator (Royall Exchanger) and financial expert to Elizabeth—among other things, forcing merchants to lend to the crown by methods that were akin to holdups yet

Stuart Mill himself could not have suggested a workable alternative, and if he rose from the dead to deny this, we should reply that he did not know enough about the conditions of the time and that it was he who laid himself open to the charge of erroneous reasoning by denying it. But this does not alter the fact that those defensible practical views are generally believed to be associated with inadequate or even downright nonsensical theories. However, the question arises whether there was any theoretical argument at all.

In fact practically all the writers who discussed the possibilities of protecting the national exchange and securing an influx of gold and silver money or bullion without reference to the balance of trade or of payments should not be credited or charged with *any* theory.[5] Precisely in order to be just to them, we must realize how innocent they were of analysis. This will clear them of some accusations which it has become a tradition to direct at them for no better reason than that we take their utterances too seriously and insist on pinning them down to theories these utterances seem to imply. But they did not analyze at all. They had no conception of any but the most obvious relations between economic phenomena. Living at a time when nations braced themselves to match their fighting power, they impulsively resented imports of unnecessary luxuries—that does not imply considered rejection of Adam Smith's grand commonplace that consumption is the 'sole end and purpose

---

were so handled as to enhance instead of annihilate public credit: the interested reader should refer to J. W. Burgon's *The Life and Times of Sir Thomas Gresham* (1839). [See also Raymond de Roover, *Gresham on Foreign Exchange* (1949).]

We may use this opportunity to notice the two analytic achievements that have been placed to his credit. First, he described correctly enough the rules that apply to the movements of the rate of exchange with reference to the specie points, and he holds priority over Davanzati, who however did a much better job in 1582. To make scientifically articulate a piece of business practice, however well known in the business community, is a service that always deserves recording. Second, there is Gresham's Law, the proposition that if coins containing metal of different value enjoy equal legal-tender power, then the 'cheapest' ones will be used for payment, the better ones will tend to disappear from circulation—or, to use the usual but not quite correct phrase, that bad money drives out good money. This phrase occurs in the Royal Proclamation 'decrying' base silver coin in 1560, when Gresham is known to have been the government's chief adviser in such matters. There is also a memorandum of his (1559) which argues this case. The so called 'law' can be found in many earlier writings. Considering its trivial nature, the question of priority is, however, without interest.

[5] It would be apt to call them Primitives (Richard Jones, 'Primitive Political Economy of England,' *Edinburgh Review*, 1847), provided we bear in mind that the primitivity was in the analysis rather than in the practice. The usual term is Bullionists, which I want to avoid because it suggests—as well as do others that have been offered (see E. R. A. Seligman, article 'Bullionists' in the *Encyclopaedia of the Social Sciences*—that there were doctrinal nostra by which to identify them as a distinct group. They were not really a group. Such views as they had in common are also to be found, on a somewhat higher level, among writers with whom nobody would include them.

of all production.' They looked at the antics of exchange rates and attributed them to the machinations of speculators—exactly as the politicians and the public did in France and Germany after 1919. They felt it was nice for a nation as well as for individuals to have money—and said so without thinking any more about it. They were staunch nationalists—and the foreigner, of course, was an object of aversion and distrust. They were most of them what may be termed naively critical of business and of the doings of merchants—as public opinion always was and is. The reader will have caught the point and will excuse me from going on with this argument. Nor would it serve a useful purpose to present examples.[6]

There were, however, exceptions.[7] The only one to call for specific attention is Malynes[8] whom we have met before. Behind his recommendations—mainly higher import duties, prohibition of bullion exportation, the staple system, and resurrection of the office of Royall Exchange for the purpose of fixing exchange rates officially—there is more serious theory than has been admitted by a long series of critics who have treated his views with contempt. That he does not merit this, is proved by the fact that, as we shall see, during the whole of that century no other writer surpassed him in clear and full understanding of the international mechanism of foreign exchanges that works through price levels and gold and silver movements—the 'automatic mechanism' to be discussed presently under the heading Balance of Trade. In the Second Part of his treatise, *Canker of England's Commonwealth,* he nicely explains how, if a country's currency falls below its mint par and coin flows out in consequence, then prices will fall in that country and rise abroad 'where our mony concurring with the monies of other countries causeth plenty, whereby the price of forreign commodities is aduanced.' This is a considerable theoretical contribution. We must go to the eighteenth century in order to find the argument carried to the conclusion to which it points. Why then did Malynes fail to draw this conclusion himself? I think because he was much more impressed with the shortcomings of that mechanism than he was with the mechanism itself. In particular he complained that, in the small and inhibited markets of his time, operations in exchange so worked out for England that she was selling her goods more cheaply and paying for foreign goods more dearly than was necessary—that is, that her terms of trade were unnecessarily unfavorable—'wherein chiefly consisteth the . . . overballancing.' He perceived the possibility of improving those terms by exchange control (our point (f) above), and further proof that he reasoned correctly upon the matter is provided by the fact that, in considering the objections to his plan (*Canker of England's Commonwealth,* Third Part), he mentions first the effect on sales that might be expected from better terms of trade and promptly replies 'how necessarie our commodities are and what request thereof is in all places'—which means that, in his opinion, foreign demand for English goods was inelastic. Now he may have been wrong in his factual appraisal of the situation. It is even certain that he overestimated both what speculation in exchange can do to harm the interest of a country and what exchange control can do to further it. Overstatement of his point is obvious in the controversy with Misselden. But that is not the point. We are not concerned with the question whether England 'should have' accepted his advice. We are concerned with his reasoning. And this, though of course not above criticism, must be primarily listed as a contribution. If we label him a 'bullionist,' then the balance of the theoretical argument is not clearly against bullionism. Nor is it true that, so far as his theoretical position is concerned, he was dislodged by Misselden.

---

[6] The reader who feels any inclination of this kind is referred to the articles by R. Jones and Professor Seligman quoted in the preceding footnote and to Professor Tawney's introductory essay in his edition of Thomas Wilson's *Discourse upon Usury* (1925). Still it may be well to mention one name at least: Thomas Milles, the customs official, who like a good bureaucrat craved for the regulated trade of the staple, which he describes as the 'first steppe towards heaven,' and for the import of bullion, which he describes as the sun, the pilot, and the 'chylus' of economic life. His least immature work: *The Mysterie of Iniquitie* (1611).

[7] Such were Marc' Antonio De Santis (*Discorso intorno agli effecti che fa il cambio in regno*, 1605), who owes survival to Antonio Serra's attack upon his theory (see T. Fornari, *Studi sopra Antonio Serra e Marc' Antonio De Santis*, 1880); Sir Thomas Culpeper, who in his *Tract against Usurie* (1621), which has been mentioned already, approached exchange transactions *per analogiam* of usury as did others and as the scholastic writers had done; the anonymous author of *Cambium Regis: or, the Office of His Majesties Exchange Royall* (1628); Miguel Caxa de Lerucla (*Restauración de la antigua abundācia de España*, 1631); and quite a number of other Spanish writers. None of these, however, went below the surface or beyond the mere mechanics of the regulation of exchanges.

[8] Gerard de Malynes (fl. 1586-1641): *A Treatise of the Canker of England's Commonwealth* (1601); *Saint George for England, Allegorically described* (1601); *England's View, in the Unmasking of two Paradoxes: With a replication unto the answer of Maister John Bodine* . . . (1603)—a contribution to the controversy between Bodin and Malestroit, in which without really attacking Bodin's argument, Malynes reasserts the importance of his argument about 'overballancing.' Mainly these three publications (and, perhaps his big compilation of legislative material, *Consuetudo, vel, Lex Mercatoria*, 1st ed., 1622) are of importance at the moment, but I may just as well add the two by which he crossed swords with Misselden: *The Maintenance of Free Trade* . . . (1622), and *The Center of the Circle of Commerce* (1623).

[4. THE BALANCE OF TRADE]

Turning, finally, to the third topic, the proposition that a favorable balance of trade[1] (excess of exports over imports) is a highly desirable or even necessary thing at which to aim, we first observe that, as regards the practical argument, much of what has been said before applies with equal force to this case. This is as true if we look at the commercial policies of that age merely under the aspect of protectionism as it is if we choose to emphasize specifically the balance-of-trade aspect. For, as has been stressed sufficiently, I hope, the war-economy and the power-politics elements in those policies would in themselves be quite sufficient to remove any tinge of *irrationality* from a wish to secure as large as possible an influx of universally acceptable money. Therefore the only question to raise is the one concerning the theoretical argument. Let us split it into two parts: (a) how far did the 'mercantilist' economists themselves take account of that association of both their recommendations and their arguments with the conditions of their time which imparts logically defensible meaning to the latter, though it does not of course—never forget this—'justify' them in any other sense; and (b) what did they contribute to economic analysis or else what provable errors did they commit in their reasoning?

---

[1] The term turns up during the first decades of the seventeenth century (Francis Bacon used it in 1615; see Spedding's ed., *Letters and Life,* 1872, vol. VI, pp. 22-3, a reference I owe to Professor Seligman's article; see also W. H. Price, 'The Origin of the Phrase "Balance of Trade,"' *Quarterly Journal of Economics,* vol. XX, November 1905, p. 157). In Italy it seems to have been used before; see C. Supino, 'La scienza economica in Italia della seconda metà del secolo XVI alla prima del XVII' (*Memorie della Reale Accademia delle Scienze di Torino,* 1888). However, there were several synonyms in use before that. The earliest instance of the concept's playing any role in an argument occurs so far as I know in the important tract (to which reference

[(a) *The Practical Argument: Power Politics.*] There cannot be any doubt concerning the first question. 'Mercantilist' writers—least of all the Italians, of course—were keenly alive to the power-politics element, as in fact they could not have helped being. In England in particular, the City from which most of the leading writers hailed was a pillar of aggressive foreign policy which, as is abundantly clear from what has been said before, suited the business interests to perfection even where it was not directly inspired by them. Of course this is not always explicitly stated. Imperialist urges rarely are. But it lurks behind the concern of our authors about the wealth of the king, behind their talk about the decay of the English power,[2] behind their fears for

---

will be made again): 'Polices to Reduce this Realme of Englande unto a prosperus Wealthe and Estate' (1549), publ. in *Tudor Economic Documents*, ed. R. H. Tawney and E. Power, Vol. III (1924), p. 311 et seq. The term used is 'overplus.' Professor Viner, op. cit., p. 9, mentioned also several others; but I do not think that Malynes' 'overballancing' refers to the same thing. How could it, since Malynes, when confronted with it in the controversy with Misselden, thought it an innovation and a valueless one to boot?

A difficulty should be mentioned here. Balance of trade in many instances stands for balance of commodity trade. Very early however, as will be explained in the text, a full list was produced of all the items of the balance of payments and it is safe to say that much of the reasoning of those authors referred to the latter. They were surprisingly slow, however, in inventing a separate term—Sir James Steuart has 'balance of payments' in 1767, though Pollexfen has 'balance of accompts' in 1697 (see Viner, op. cit. p. 14)—and meanwhile often spoke of balance of trade when they meant balance of payments. We shall always assume this when the argument requires it. There is a special reason why we may do this: under the circumstances of the time, the balance of trade was the most important item and also the one most amenable to management. Hence an author whose real concern was the balance of payments may well have concentrated on the balance of trade.

[2] Complaints about that decay were so frequent as to constitute a most interesting phenomenon of political psychology. Little of what we may term social psychoanalysis

England's safety, behind the attitude that Hume was to criticize in his essay *Of the Jealousy of Trade* (1752), behind their insistence on the vital importance of the navy and, in connection with it, of shipping and shipbuilding. Of special interest, however, are those cases in which the power (or safety) argument is not only put forth unmistakably but is also opposed to the profit argument: for whatever we may think of this from other angles, it marks progress in economic insight. Two well-known examples will suffice. In his *Discourse about Trade* (1690) Child defends the policy of the Navigation Acts by the power argument while admitting that, from a purely economic point of view, there may have been a strong case against them. In his *Discourses on the Publick Revenues and on the Trade of England* (1698), Davenant goes further still.[3]

[(b) *The Analytic Contribution.*] To answer the second question—the one about contributions to, and errors in, analysis—is not so easy. Some contributions there are. They will present themselves in the proper light if we look at them, as it were, *ex ante*, and not, as critics invariably do, from the standpoint of later analysis for which it was the most important contribution of the 'mercantilist' writers to have paved the road and which in fact grew out of their work. But as soon as one dives into that literature, one cannot fail to be struck by two things.

---

is required in order to understand what it meant. Parallel with them went complaints about a wholly imaginary economic decay—in the mind of the merchant class, power and prosperity were of course inextricably associated—which were characteristic of a large group of writers: Fortrey, Coke, 'Philanglus,' Bellers, and Pollexfen may be mentioned as examples.

[3] The nature of that antagonism between power and profit does not seem to have been always understood. Some critics, especially those who see nothing in the writings of the English 'mercantilists' except 'special pleading' for class or even personal interests, have argued that the power argument can only have been introduced to camouflage the profit interest and that the scribbling merchants must therefore have believed in the balance of trade argument independently of the power element. I think that this is bad sociology—we only impair our diagnosis by shutting our eyes to the fact that the imperialist urge is a stark reality that roots in other soil than that of the economic self-interest of the individual. But even disregarding this, we must distinguish two quite different things *within* the argument inspired by business interest: power and profit may conflict as regards immediate results and yet power may eventually lead to still higher profits, especially in an age of buccaneering imperialism. Hence there is no contradiction between the perception that the balance-of-trade argument, on the first plane of reasoning, needs support from the power argument, and the proposition, on the second plane of reasoning, that the power argument issues in *another* profit argument in the long run. I can see no point in sneering at Child's formula: 'foreign trade produces riches, riches power, power preserves our trade and religion' (with Louis XIV on the other side of the channel), but the argument can, if critics so wish, be made purely economic and still remain tenable, with the balance of trade in no other role than that of an intermediate link. [A long essay by J. A. S., 'Zur Soziologie der Imperialismen' (*Archiv für Sozialwissenschaft und Sozialpolitik*, 1919), bearing on this subject, is now available in English: *Imperialism and Social Classes* (ed. with introd. by Paul M. Sweezy, 1951).]

First, though pieces of genuine analytic work can be found occasionally and attempts at analysis more frequently, the bulk of the literature is still essentially preanalytic; and not only that, it is crude—the work of unprofessional or even uneducated minds that frequently lacked the rudiments of the art of exposition: much of that literature was popular in the most distressing sense of the word. Perception of this fact, of which some of those writers were themselves painfully aware, should not only teach us forbearance, particularly with respect to individual *dicta*—on the strength of which an author should never be condemned until we have satisfied ourselves that he actually makes improper use of them—but should also warn us that we are in constant danger, reasoning from our own sublime heights, of misunderstanding what those simple fellows really wanted to say. To be sure there are a considerable number of writers to whom this does not apply. But this only leads up to another difficulty. If we want to be just to the age, we must clearly separate substandard chaff from valuable wheat. How will the economics of our own age come off two or three hundred years hence, if critics take it into their heads to judge it by everything that has been written on economic subjects during the last decade? But what, beyond a rather small group of performances on which we may all agree, is the wheat? Here, every one of us must rely on his personal evaluations of analytic quality—the only kind of value judgments that are both permissible and unavoidable in a history of scientific economics—a matter in which often the only agreement attainable will be the agreement to differ.

Second, we have had ample opportunity already to observe that the views of the economists of that period—if indeed it be permissible to speak of economists at all for a period in which the profession was in process of emergence but had not really emerged as yet—were as uniform as are those of the economists of any other period but that they were not more so: individuals and groups differed from one another, in fundamentals and in details, as much as economists always have, and they fought one another's views and methods accordingly. The widespread opinion to the contrary has resulted in another injustice. The critical historian, after having set up a 'uniformed' man of straw, misses the fact that much of what is most objectionable from the standpoint of later analysis (or politics) had been rejected or corrected within the period. The historian has indeed a method of dealing with this fact when it stares him in the face: those who took what to him seems to be a more correct view are either visited with more lenient strictures or else they are excluded from that imaginary unit under the heading of heretics or forerunners. But this method is a doubtful one to say the least.

We have noticed, and tried to understand, the protectionist current of the times; we have also encountered the opinions that a number of writers held on the subject of protection. We shall naturally expect the writers we are considering under the heading of Balance of Trade to have completed the list of protectionist arguments. This expectation is not disappointed. We find the infant-industry argument, which, excepting perhaps the case of English woolens, must in the circumstances of the period be assumed to underlie any recommendation of protection to domestic industry that is not expressly motivated in a different way. We find the military, the key-industry, and the general-autarky arguments. We find the employment argument. We find the argument that today has come into such prominence in connection with the multiplier approach, namely, that so far as protection succeeds in producing an excess of exports it will stimulate the business process by increasing domestic expenditure. Foreign investment plays no role, or next to none, in their analysis except in a short-run sense: some of them pointed out that a temporary export of coin may be a necessary link in a series of transactions that eventually nets an export surplus. English instances—we shall confine ourselves to English ones although the Continent would also furnish a crop—are given below. They will also add to our modest collection of names.

As we should expect, the infant-industry argument turns up in the times of Elizabeth, when England experienced her first industrial boom, and pervades the literature under discussion to the end, that is, to the threshold of the industrial revolution, when Sir James Steuart put considerable emphasis on it. We are primarily interested in cases where protection is recommended only for a limited time or where the element of 'infancy' is otherwise stressed in such a way as to remove any possibility of doubt about the character of the argument. Thus, Arthur Dobbs in *An Essay on the Trade and Improvement of Ireland* (1729-31), Part II, expressly stated that 'premiums are only to be given to encourage manufactures or other improvements in their infancy' and that further help would be in vain 'if after their improvement they cannot push their own way.' Yarranton (*England's Improvement by Sea and Land, to Outdo the Dutch without Fighting, to Pay Debts without Moneys, to Set at Work all the Poor of England* . . . 1677, 2nd part, 1681) recommended protection to linen manufacture but only for a period of seven years. Andrew Yarranton found a biographer enthusiastic enough to call him 'the genuine founder of political economy in England' (see P. E. Dove, *Elements of Political Science*, 1854, App.). Although this is of course absurd, it was perhaps a healthy reaction against the neglect that had fallen upon his name. Yarranton was a versatile man of many trades and cannot, in some of the lines of his activity, agricultural technique in particular, be rated higher than as a popularizing projector. But in economics he was more than that. Though there are no analytic conquests to his credit, many of his suggestions and many of his comments on German and Dutch conditions imply a theoretical schema; so does the fact that, even in his most daring flights, he consistently stops short of nonsense. He paid little court to the balance of trade. He believed that the prosperity of neighboring countries was a gain to England. Improvement of credit facilities would reduce the rate of interest from 6 to 4 per cent (observe the limits which guard the statement against an indictment that without them would be dangerously near at hand). Employment and cheap food (the latter being sure to make cheap products [he says 'cloth']) are the goals to aim at. In fact we can herewith quote him as an authority for all the arguments mentioned in the text, as we have quoted him and shall quote him on other topics.

The military argument has been dealt with already. The key-industry argument is present in the discussion on foodstuffs and the production and exportation of wool. The general-autarky argument was developed in Germany rather than in England (for France, see J. Nowak, *L'Idée de l'autarchiè économique*, 1925). For the employment argument we have just had an example in Yarranton. It occurs from the first (see Clement Armstrong, 'A Treatise Concerning the Staple and the Commodities of this Realme,' *c.* 1519-35, *Tudor Economic Documents*, III, pp. 90 et seq., especially p. 112; see also John Hales, *Discourse of the Common Weal*, 1549?). Protectionist legislation, motivated by the unemployment argument, is of course still older by at least a hundred years and is rarely absent from the more considerable books. Malynes, Misselden, Child (who makes it the criterion of the advantage that accrues to the mother country from colonies), Barbon, Locke, Petty—all have it. Let us notice in addition: John Cary, *Essay on the State of England . . .* (1695), which to judge from its being reissued a number of times and from Locke's commendation must have been a considerable success; John Pollexfen, whose whole case for prohibiting the exportation of wool and the importation of manufactured goods is based upon the employment argument; John Bellers, *Essays About the Poor, Manufactures, Trade . . .* (1699); and 'Philanglus' (W. Petyt), *Britannia Languens or A Discourse of Trade* (1680). Some of the 'mercantilist' writers went to surprising, in fact to Keynesian, lengths. There is nothing startling in Sir William Petty's saying that it is better to produce useless things than not to produce at all: this only shows his concern about the conservation of the efficiency of labor. But others sometimes expressed themselves as if they thought that the national advantage to be reaped from foreign trade consists exclusively in the employment it gave. And this in turn logically led to that position which looks so absurd when judged from the assumptions of the nineteenth century 'liberals,' and has in fact been called absurd by Professor Viner (op. cit. p. 55; the reader finds examples on the two preceding pages), namely, that a trade is the more advantageous to a country the *higher* is the total labor cost of the exports as compared with the total labor costs of the corresponding imports. To one aspect of this we shall return.

The employment argument was not only advanced per se, but also in its indirect form, via the stimulus which inflowing cash will give to business. Here we are not concerned with all those writers who considered the possibility of imparting this stimulus by the creation of paper money, but only with those who thought of lubricating the wheels of business by means of the importation of coin and bullion. If the reader observes how very popular this idea is and always has been with the man in the street, he will expect that it is practically ubiquitous, so much so that it often is implied rather than explicitly stated. The only obstacle to its absolute sway was the treasure aspect of bullion importation—the idea that the imported bullion should be hoarded against the requirements of war. Malynes and Misselden, the two antagonists, may however both be quoted as instances of this 'lubrication argument.' Both saw the stimulus in connection with rising prices. Malynes' shade—after having been, for three centuries, the object of practically universal vituperation—drawing applause from Lord Keynes (*General Theory of Employment, Interest, and Money*, p. 345) for being aware of 'the fallacy of cheapness' and the danger of 'excessive competition' and for having associated increasing sales with rising, instead of falling, prices. But, as we have seen, other writers did not stress this relation of the stimulus with rising prices: they either looked upon higher rising prices with misgivings or else they believed that bullion importation would stimulate trade without raising prices. That it is by no means foolish to hold the latter opinion will be shown later in a footnote.

Child, Mun, and others afford examples of the proposition that foreign investments are inevitable in the short run—if they said so from interested motives, what of it?—but I am unable to quote instances of arguments in favor of permanent investment abroad before Sir James Steuart and, what is more, neither is Professor Viner (op. cit. p. 16).

So far as these arguments are concerned, there is little serious error to record. Considering the pattern to which they were to apply, they were all more or less capable of logical defense—more, in some respects, than are the similar arguments of today. Moreover, certain weaknesses should not be judged too severely. It is true, for instance, that most of those writers do not seem to have been aware of the extent to which the validity of their arguments, at least of the purely economic ones among them, depended upon the condition of underemployment or *underdevelopment* of productive resources.[4] But the reverse reproach may be addressed to their critics and successors in the nineteenth century, in part even to Marshall himself.[5] Finally we shall see that many of the necessary qualifications and many of those counterarguments that are complementary rather than competitive were worked out not by a few isolated 'heretics,' but by the 'mercantilist' writers themselves.

But neither is there much analytic merit to record. Whether right or wrong, those arguments were in most cases put forth on the strength of their common-sense appeal. The common man at all times believed in them as a matter of course, and the economists of that age believed in them along with him. They tried to rationalize the practice of their time, both in the sense that they tried to voice what they conceived to be the aims and needs of their times and countries, and in the sense that they tried to put some logical order into the irrational heap of actual measures and practices. But they did not probe below the surface to depths where the need for analytic technique asserts itself. They posited their arguments and hurried on to specific recommendations, for example, as to which industries were the most promising ones to foster—for England, they suggested fishing or iron or linen or the improvement of waterways or the development of crown lands—and how the government should go about fostering them: many of their works are just full of projects—Yarranton's are a good example. But as a rule they did what our own planners mostly do: they left off where analysis begins. This is what I meant when I said that the bulk of that literature was pre-scientific, which from our point of view is much more important than whether we like or dislike 'mercantilist' policies and their nationalist spirit. How very pre-scientific the reasoning of most writers was can be seen most clearly where they did make attempts at analysis and nowhere better than in the way they handled the one analytic tool that hostile historiography has singled out for criticism, the balance-of-trade concept.

---

[4] Compare, however, Arthur Young, *Political Essays concerning the Present State of the British Empire* (1772), who (p. 533) explicitly refers to 'unemployed poor and unpurchased commodities.' I owe this reference to Professor Viner (op. cit. p. 54).

[5] Marshall, and also Pigou, did relax on the 'absolutism' of traditional free trade doctrine, especially in their contribution to the controversy about Joseph Chamberlain's tariff-reform proposals. But they hardly made it sufficiently clear to others, and may not have sufficiently realized themselves, that the usual propositions about free trade are only valid under conditions that often fail to be fulfilled or, alternatively, only on a high level of abstraction.

We may use the opportunity to touch upon another point that has been made. It has been held that, as is indeed obvious, the 'mercantilist' writers presented short-run views and it has been admitted 'that some of the mercantilist doctrine would not be quite so absurd if appraised from the short-run point of view' (see Viner, op. cit. p. 111). But there is no 'evidence that the mercantilists intended their analysis and proposals to be regarded as holding true for the short run only, and there is abundant evidence that they were ordinarily not aware of any distinction between . . . desirable . . . practice to meet a temporary situation . . . and . . . permanent policy.' (ibid.) This is hardly fair. The distinction alluded to is a result of prolonged analytic work; it would be easy to mention examples of its violation from later and even from modern work. The mercantilist writers wrote for the situation that confronted them much as did Lord Keynes. This was, to be sure, not a temporary situation in the narrow sense—it was the situation of an age which was a sequence of emergencies and in which analysis of long-run equilibria could have interested only the purest of pure theorists. But they did not talk about any 'permanent' policy either. They were too practical-minded to believe in any such thing or rather this idea had not entered their heads at all. Apart therefore from passages (e.g. in Thomas Mun's *England's Treasure,* to be quoted later) which indicate that some of them did have an inkling of the fact that, as we should say, their argument did not apply in the longest run, let alone to a state of long-run *equilibrium,* it should be enough for us to judge their argument as it stands, whatever their own opinion of its methodology may have been.

[(c) *The Balance-of-Trade Concept as an Analytic Tool.*] The first thing to observe about this concept is that it is in fact an analytic tool. The balance of trade is not a concrete thing like a price or a load of merchandise. It does not obtrude itself upon untrained eyes. A definite analytic effort is required to visualize it and to perceive its relation to other economic phenomena, however insignificant that effort may be. The history of theoretical physics shows that achievement of this kind is difficult and takes much more time than we should expect: ideas have for centuries been within what to us seems easy reach, and they have even been uttered in some sterile form from time to time without really coming fully within anyone's grasp. If we reflect upon this difficulty we shall cease to make light of that particular achievement.

Nor does the concept lack importance. The balance of *payments* in the sense defined in the footnote below[6] is an important datum in the diagnosis of the economic condition of a country and an important factor in its business processes. In the seventeenth and eighteenth centuries the *balance of trade* in commodities and services may well have been the operative part of the *balance of payments* and, thus, have had all the importance that may be attributed to the latter. The trouble with it is that, as a tool of general economic analysis, it does not work by itself: if we know nothing except the figures of exports and imports (always including figures for services), we cannot make any inferences from them. Thus, an 'unfavorable' balance may be the symptom of increasing wealth but also of a process of impoverishment; a 'favorable' one may mean prosperity and employment, but just as well the reverse. It is only in connection with other data that the balance of trade acquires both its symptomatic and its causal meaning. This should perhaps be qualified by the admission that, even taken by itself, the net of the balance of current debits and credits—which sometimes *may* be approximately indicated by the current net of the balance of trade—is an important factor in the monetary processes of a country, hence an important factor in the decisions of monetary authorities. But broadly speaking, reasoning as well as action that turns on nothing or next to nothing but the balance of trade cannot be correct except by accident. These considerations will help materially in appraising both the contributions and the errors of the 'mercantilist' writers. Let us keep in mind, however, that now we are not concerned with a plank in an economic platform but with the handling of an analytic tool.

---

[6] I take it that the kind of statement that we refer to by this term (Balance of Payments) is familiar to the reader and that he properly distinguishes it from the balance of indebtedness. But there is one point about it on which it may not be superfluous to comment. The statement might be drawn up according to ordinary bookkeeping principles. In this case, there is for every item that enters the balance sheet another item that will balance it as a matter of bookkeeping technique. Such a balance would always 'balance,' not only necessarily, but tautologically. But even if we simply confront the sum total of credit items with the sum total of debit items, the two totals must eventually be equated somehow, if necessary, by carrying forward, or defaulting on, the difference. In this sense the balancing is still necessary though it is no longer tautological. There is, however, a third sense in which credit and debit need not balance in either of these two meanings, but are made to balance by forces which their failure to do so will automatically set into motion—so that (but in a third sense) we may still say that they will balance 'necessarily.' The households and firms of countries A and B, which for simplicity's sake are now both assumed to be on a perfectly free gold standard and to have no other dealings except sales and purchases of commodities, may send out orders to each other that will at any given point of time sum up to different amounts. But as these orders are being carried out and paid for, any such difference will, in the absence of credit arrangements, have to be settled in

[(d) *Serra, Malynes, Misselden, Mun.*] This analytic tool has a long prehistory into which we need not go.[7] Credit for having had a clear conception

---

specie, and this flow of monetary metal will (or would eventually, if there are absolutely no hitches, if prices are flexible, etc.) so act upon prices and incomes (to neglect everything else)—and these variations in prices and incomes will in turn so affect the orders, hence the commodity flows—as to bring about 'automatically' equality of debit and credit items and a distribution of the gold that will be adequate to support the prices resulting from the process. This primitive schema represents what we mean by the Automatic Mechanism, which was, as we have seen, described—partly at least—by Malynes and which will presently be used as one of the guiding stars in our travel through part of the 'mercantilist' literature. If we have sufficient confidence in its strength—miraculous though such confidence would be in people who have been witnesses to the world depression—we may be so little impressed with the danger of its failure to function as to hold that it will always insure that equality. This may then be expressed by saying (rather misleadingly) that balances of payment will 'necessarily' balance if we include the balancing gold flow. Note, for the time being, that in the text the term balance of payments should be understood to exclude this (or any other) balancing item, so that there is no *need* for debits and credits to balance.

[7] An instance of its use at the middle of the sixteenth century has been given in footnote 1, at the beginning of this section. Other instances could be mentioned even from much earlier times. Thus in 1381 an official of the name of Richard Aylesbury expressed the opinion that no money would flow out of England if not more 'strange merchandise' were allowed to enter England 'than to the value of the denizen merchandise which passes out of the realm.' He also supported the policy of prohibiting exportation of coin (and importation of debased foreign coin) and, displaying aware-

of it and for having been the first to use it fully and, in substance, correctly belongs to Antonio Serra.[8] It is not only that he paid due attention to the invisible items, in which he seems to have anticipated all writers of his own century; or that he fully realized the nature of exchange-control policies; or, as it is usual to put it, that he 'refuted the bullionist doctrine of the exchanges'; or that he expounded (as had Laffemas before him) the views about the prohibition of gold and silver exports which in England were to become general, at least among the writers of first rank,[9] as the century drew to its close; or that he introduced the quantity-theory element into the discussion concerning the proposal to stop the outflow of gold and silver by devaluation—although these were important contributions. Nor should we allow ourselves to be too much impressed by the fact that, though not the first to see the relation between gold and silver movements and the balance of trade (or payments), he was the first to elaborate it. For though this does carry analysis one step further, in itself it does not mean more than a rather obvious observation, which moreover is just as likely to suggest wrong or at least inadequate inferences as it is to suggest true ones. The really important point is not that he explained the outflow of gold and silver from the Neapolitan Kingdom by the state of its balance of trade, but that he did not stop at this but went on to explain both the outflow and the balance of trade by the economic conditions of the country. Essentially, the whole treatise is about the factors on which depends the abundance of *commodities*—natural resources, the quality of the people, the development of industry and trade, the efficiency of the government—the implication being that if the economic process as a whole functions properly, the balance of trade will take care of itself and not require any specific. In this schema monetary phenomena are consequences rather than causes, and symptomatic rather than important in

---

ness of the importance of the invisible items of the balance of payments, further suggested that the payments to Rome should be effected in kind rather than in money—the same suggestion that was to some extent adopted in the case of German reparation payments in and after 1919. All this is (contrary to M. Beer's opinion in *Early British Economics*) perfectly in keeping with sixteenth century views. Source of quotation: 'Opinions of Officers of the Mint on the State of English Money' in Bland, Brown, and Tawney, *English Economic History, Select Documents*, pp. 220 et seq., a most helpful compilation, perusal of which cannot be recommended too strongly.

[8] *Breve trattato delle cause che possono far abbondare li regni d'oro e argento dove non sono miniere, con applicazione al regno di Napoli* (1613). The title, as will be seen from my comments, is somewhat misleading and the exposition of what I conceive to be his fundamental idea is somewhat impaired by this concentration on the narrow polemical purpose of refuting De Santis' exchange control views (see above, sec. 3, n. 7) in which, if we judge him from the standpoint of present-day views, he also went too far. (On Serra, see above ch. 3, sec. 5.)

[9] For the benefit of some historians of economics, it may be well to add that Serra was not a director of the East India Company, but a poor devil who wrote his tract in a Neapolitan prison.

themselves.[10] And the author (in his discussion of the case of Venice, ch. x, Part 1) brushes against, though he does not explicitly state, the proposition that a prosperous country—that is to say, a country whose economic process is not disintegrating—can have all the gold and silver money it may require.[11] From this, however, the way should not have been very far to Hume.

There are two reasons why this has never been adequately recognized. First, Serra stopped short of pointed formulation, and there were no immediate successors to develop his analysis. Second, the vision of critics, whether friendly or hostile, has been so blurred by slogans about 'mercantilism' that they hardly bothered to ask what precise role a man's protectionism played in his schema of thought and in what sense the balance of trade seemed important to him—though, from the standpoint of economic analysis, these questions are much more interesting than is the question how far removed that man may have been from free trade.

In England, a controversy not dissimilar to that between De Santis and Serra arose between Malynes and Misselden. We have already glanced at it from the side of Malynes. To a lesser extent, Edward Misselden (fl. 1608-54) [12] is entitled to credit on a par with Serra. He did not fail to state the proposition that exportation or importation of bullion is in the last analysis to be explained by the 'plenty or scarcity of commodities' and therefore cannot be accused of having missed the point entirely.[13] Nor is it as easy as generations of critics believed it to be to convict him of erroneous reasoning if, on the one hand, we fully allow for inadequacies of exposition and, on the other hand, for whatever may be said in his favor from the point of view of recent theories. Unquestionably, however, he came much nearer than did Serra to those definite errors which stand out so glaringly in Mun's book,[14] perhaps only because there the argument is more fully developed.

---

[10] The first sentences of the first chapter of Part 1 of Serra's *Breve trattato* cannot be adduced against this statement, because they are amply accounted for by the occasion and by the wish of the author to be read by the captain general, who was just then worrying about the state of the exchanges and the drain of money. I do not think that anyone who considers the book as a whole will wish to disagree.

[11] It is one of the weaknesses of 'mercantilist' literature that it never—not even at its peaks, such as Petty—got beyond the idea of a required amount of money, any excess or deficit being in the nature of a disadvantage. Serra did not even get as far as that, but merely speaks of 'abundance.'

[12] At first, that controversy was in the nature of a family quarrel between exponents of different monetary policies, for in his first publication, *Free Trade: or the Meanes to Make Trade Florish* (1622), Misselden expounded views not entirely different from those of De Santis (the meaning of Free Trade, as pointed out before, had little to do with the meaning the term acquired in the eighteenth century). Misselden meant no more than the removal of certain monopolistic restrictions, especially by the great companies, including the Merchants Adventurers to which at that time he belonged himself. But he developed, and in 1623, published his attack upon Malynes, in which he not only used the term balance of trade but placed the concept in the center of his argument: *The Circle of Commerce; or the Ballance of Trade* . . . 1623. On Misselden, see particularly E. A. J. Johnson, *Predecessors of Adam Smith* (1937).

[13] The reader will however recall what has been said above on behalf of Malynes. To that extent, commendation of Misselden must be tempered, as it must in Serra's case, by taking account of the fact that he entirely overlooked the elements of truth in his opponents' argument.

Mun's book is generally looked upon as the classic of English 'mercantilism.' This prominence is unfortunate, but it is not wholly unmerited. In fact we already have had to mention it several times. A wide variety of questions—from fishing to the gold and silver embargo—are dealt with sensibly (though without particular depth or originality) in its spacious frame, the connecting thread being what in Professor Johnson's felicitous phrase we may call concern for 'generating productive power.' [15] This aspect is, however, covered by previous comments, particularly on the protectionist argument. It is only in order to avoid misunderstanding that I wish to emphasize once more that the economics behind Mun's arguments on practical questions was, if primitive, yet substantially sound—which statement, to risk another repetition, has nothing to do with approval or disapproval of imperialist goals or any other 'ultimate standpoints.' [16] Those arguments are in fact very little affected by the analytic errors to be mentioned. Even the particular emphasis placed upon the export surplus is, as we know, in itself not incapable of defense. Finally, not only are the erroneous propositions removable, but they are in most cases, and especially in Mun's, associated with others that qualify and sometimes even contradict them. The two most important instances in his case are his recognition of the necessity of occasional gold and silver exports,[17] and his recognition—which seems to have escaped some critics—of the fact that in the end of ends a policy aiming at persistent export surpluses must defeat itself through the rise in domestic prices it would eventually produce.[18]

---

[14] Sir Thomas Mun (1571-1641) was a prominent businessman—as modern critics never fail to emphasize, he was, among other things, a member of the committee of the East India Company—who by virtue of his ability and force of character acquired considerable authority that reached far beyond the business community. If in this book we were interested in doctrines and policies for their own sake, we should have to rank him very high. Let us note his *Discourse of Trade from England unto the East Indies* . . . (1621; an important contribution to the controversies about the East India Company, reprinted by the Facsimile Text Society, 1930) and the book mentioned in the text: *England's Treasure by Forraign Trade: Or, The Ballance of our Forraign Trade is the Rule of our Treasure*, an imperfectly systematized collection of papers written presumably about 1630, and posthumously published by his son, John Mun, in 1664. There were several reprints, one in Ashley's *Economic Classics* (1895).

[15] E. A. J. Johnson, *Some Origins of the Modern Economic World* (1936), p. 98.

[16] It should perhaps be explained why, in apparent contradiction to my programmatic explanations in the First Part, I constantly refer to policies and recommendations. I shall do so less and less as we go on. But in the case of the 'mercantilist' writers recommendations and 'practical' arguments offer the only possibility of probing into an embryonic fund of theoretical knowledge.

[17] This, of course, critics found it easy to dispose of by pointing out that all he thought of was to defend silver exportation by the East India Company. It is more to the point, however, that his argument about this exportation—based as it is on re-exportation of imports from India and other factors which would tend to reverse the flow, possibly more than reverse it—does not amount to more than a qualification

The errors in question all center in a single proposition, which may, however, be stated on three different levels: (1) that the export surplus or deficit *measures* the advantage or disadvantage a nation reaps or suffers from its international trade; (2) that the export surplus or deficit is what the advantage or disadvantage from international trade *consists in*; (3) that the export surplus or deficit *is the only* source of gain or loss for a nation as a whole.

All three statements have been made. None of them is defensible. The idea that a certain quantity measures another quantity that cannot be measured directly is not one that occurs readily to the untutored mind. Therefore, we shall not expect to find explicit instances of proposition (1) and I have inserted that statement only because it affords a mitigating interpretation, justifiable in some cases of what really reads like (2). Fortrey and Coke[19] may,

---

that leaves the principle intact. We also know that the analytic progress involved was anticipated by Laffemas and Serra.

[18] Thus, Mun used the quantity theory fully as much as was requisite for his purpose. In the face of this and of what I said before in connection with Malynes' work, nothing more need be said about the indictment (which does hold for the Spanish *politicos* of the first half of the seventeenth century) that the English 'mercantilist' writers as a group, Bodin notwithstanding, had not yet discovered that theory. It is also interesting to note that, unlike some of the nineteenth century economists who felt so superior to them, the 'mercantilists' were aware of the importance of that time interval during which increase in liquid means would assert its stimulating influence on business activity without as yet raising prices. An explicit statement about this may be found in a tract which it is not possible to commend in any other respect: J. Hodges, *Present State of England* (1697), *passim*.

[19] Samuel Fortrey, a thoroughly insignificant writer, attracted much attention by his pamphlet: *England's Interest and Improvement* . . . (1663), in which he published (quite spurious) figures about England's trade with France according to which England had exported to France to the extent of £1,000,000 and imported to the extent of £2,600,000. This he called a 'loss' to England of £1,600,000, which we may, I think, take as a fair example of (1)—provided that any clear idea can be attributed to that author. But even a writer of very different caliber, who will be mentioned again, Roger Coke (the works most important for us are *A Discourse of Trade* . . . 1670, and *England's Improvements* . . . 1675), allowed himself, in an unguarded moment and scared by Fortrey's figures, to make the same statement, viz., that 'where consumption of things imported, does exceed in value the things exported, the loss will be as the excess is.' Of course, the error in question must not be assumed in every instance of the occurrence of the words 'loss' and 'gain.' For, first, they may have no other meaning than they have when we say, e.g., that the Bank of England 'suffered a loss of gold.' This is especially likely to be the case where gain and loss expressly refer to 'treasure,' which term often, though not always, means only gold and silver. Second, it should not be forgotten that, though our proposition is not valid in general, there are particular cases and meanings in which it is valid or in which the error involved is not very serious. In this connection it is especially important to bear in mind that the 'mercantilist' writers, more than their successors, actually did have particular situations in mind.

however, be quoted by way of illustration. The second statement—which of course we must not suspect behind every proposition about the advantages, real or fancied, of an export surplus—is not very easy to find in writers who count. Both Misselden and Mun seem to be among them, however—perhaps even Petty if we choose to take at face value a certain most infelicitous passage. With the small fry, such utterances as that all exports are gain, all imports are loss, are almost as common as they were with protectionist United States senators in the nineteenth century and even later. The third statement is the worst. Since no fair-minded person will lightly attribute such nonsense to any writer who displays any traces at all of ability to reason, and since inadequate formulation may easily make it indistinguishable from the harmless assertion that expansion of her foreign trade was, for seventeenth-century England, an important avenue to greatness (purely rhetorical overstatement was much more usual in the times of Euphuism, Marinism, and Gongorism than it is today), it would be tempting to deny the existence of convincing cases. The reason why this is not possible does not so much lie in the fact that some instances would prove rather refractory to benevolent interpretation, but rather in the fact that such attempts at analysis as were undertaken would, if they had been successful, have established the third statement along with the two others.

The most common of these attempts proceeded by way of analogy. Its most influential, though not its first, sponsor was Mun (and it was repeated by Cary). If an individual adds part of his annual income to the ready money in his chest—provided, so we must add, the others do not do the same thing—he will grow richer every year; if a nation realizes an export surplus and draws it in gold and silver, it is doing the same thing; *ergo* the nation will be enriched by the exact amount of this surplus. Let us remove some of the most obviously objectionable features of this piece of reasoning by choosing a somewhat different analogy. Suppose we look upon a nation as a business concern. A private firm may be said to grow richer or poorer every year by the amount of the profit or loss item of its balance sheet. Suppose further that the balance of payments is for the nation what the ordinary balance sheet is for the individual firm, so that its net corresponds to the latter's profit-and-loss item. If the balance of payments contains nothing except the elements that make up the balance of trade, the nation would grow richer or poorer every year by the amount of its export or import surplus. Two things are clear: first, that there is no sense whatever in this argument; second that, if it be taken seriously, then all three of our statements would follow and not only the first two.[20]

---

[20] Attention should be called to the fact, overlooked by at least one critic, that the phrase 'a nation is not enriched by what is purchased for consumption at home' does not necessarily involve statement (3). For it *may* mean no more than this: if A buys from his connational B some goods for his own consumption, then, in a central bookkeeping agency of the nation, A would be debited and B would be credited with equal amounts; if however B sells the goods to the foreigner C, then B would still be credited but there is no compensating debit—a triviality which may invite, but does not in itself spell, error.

Even if not explicitly stated, some such confusion must be suspected whenever the favorable-balance element is stressed in the absence of a special motivation, such as the argument about monetary stimulation of the business process. There is, however, another line of reasoning that may lead up to the first two statements and even entangle an author in the third. Several authors of high rank, such as Coke and Petty,[21] adopted it, but it was most clearly developed by Locke.[22] If we define national advantage to mean increase of the relative share of a nation in the world's real wealth, and if we suppose that all countries use an unfettered silver standard, the total amount of silver in existence being approximately constant, then the nation's relative share in the world's wealth will tend to be proportional to, or represented by, its relative share in the existing stock of silver. 'Riches do not consist in having more Gold and Silver, but in having more in proportion than the rest of the World,' which is why a certain quantity of silver, if acquired by means of a favorable balance of trade, increases the riches of a nation more than would the same quantity if newly mined. Disregarding the latter possibility, we may even say that a favorable balance of trade is the only means of increasing that share in the world's wealth or, for any nation, the only possible source of additional 'relative wealth,' a proposition that is not worse than many that are taught today. It is strikingly illustrative of the ways of the human mind that Locke of all men should have committed himself to this argument. That Colbert[23] should have been addicted to it is much less surprising.

[(e) *Three Erroneous Propositions.*] Before we go on, it is necessary to touch briefly upon three points of minor importance. First, if the argument just presented were acceptable, it would provide a rationalization for the idea that one nation's gain is another nation's loss. In fact this idea would simply follow from it. However, much as we stand in need of such a rationalization of an idea that was current at that time and has never been absent at any time, we are under no compulsion to assume that it was rationalized in that way. Bearing in mind the primitivity of all the economic reasoning of the period, we may perhaps more plausibly connect that idea with its counterpart in the realm of individual economics, the idea that in every exchange one man's gain is another man's loss. From Aristotle on, philosophers refined upon it by defining more precisely what the gain was that thus came under a ban, namely, the surplus above the just price. But however it was defined, the people always felt, as they do now, that the kind of gain that made the merchant rich resulted from their being somehow cheated or exploited. In the writings of the Consultant Administrators of all types, symptoms abound both that they more or less subscribed to that view and that gradually they were getting rid of it. Few subscribed as explicitly as did Montchrétien, who states it as an axiom (Heckscher, op. cit. vol. II, p. 26); few got over it as completely as did Barbon: the bulk of the literature is between these extremes. This slow disintegration of one of the oldest elements of popular economic thought is one of the most important points to remember concerning the history of analysis in the seventeenth century.

---

[21] I do not think, however, that Petty (*Verbum Sapienti*, ch. x) meant anything to which very strong objection need be taken.

[22] *Some Considerations* . . . (1692), see above, ch. 6, sec. 2. He also uses the analogy just discussed.

[23] See Heckscher, op. cit. vol. II, p. 27.

Now, if we take hold, on the one hand, of the principle that 'one man's gain is another man's loss' and, on the other, of the habit of the period of reasoning on national trading by analogy with individual trading, we arrive immediately at another faulty rationalization of the belief that one nation's gain must be another nation's loss.

Second, from this follows immediately a possible explanation of another erroneous proposition that may be suspected behind many versions of the balance-of-trade argument. If we identify the gain that is somebody else's loss with profit in the businessman's sense, then all such gains will cancel out in a combined balance sheet of all firms and households in the country, *except* the gains that are made in foreign trade. These will not cancel out, because foreigners' losses do not count. Making the further wild assumption that these gains add up to the export surplus, we may cap a pyramid of nonsense by asserting that the latter represents the sum total of net—that is, uncompensated—private profits in a nation.

But I am not prepared to charge this to the account of any of those 'mercantilist' writers who were on a level sufficiently high to warrant the discussion of their views, even if some of them did come dangerously near to saying or implying it. My reason is that the Consultant Administrators did not primarily write—whatever they may have thought—about individual profits. Even when they used terms such as 'profits' from international trade, they meant national advantage. And this national advantage was not identified with the profit interest. Nor was it held that individual action on the profit motive, necessarily or normally, promotes the social or national interest. This laissez-faire proposition was at first quite foreign to their scheme of thought. They used the principle that business behavior turns upon profit—for instance, their recommendations mostly aim at influencing profit expectations—but they not only admitted the possibility of clashes with the public interest, they even considered clashes to be normal and concordance to be exceptional. This is precisely why most of them took the necessity of government regulation for granted and only discussed the aims and methods of it. It is true that they slowly worked their way toward a different point of view—as we shall see presently, one of their achievements consists in this. But fundamentally they were planners, planning precisely in order to avoid what they conceived to be the antinationalist effects of unregulated enterprise, irrespective of how profitable such enterprise might be to individuals: when they recommended that the importation of currants via Venice should be stopped, they did not bother about the profits that might be destroyed by so doing. Under these circumstances it is hardly necessary to insist on fastening upon them the responsibility for that particular analytic miscarriage.

Third, nothing has been said so far about the famous 'confusion of wealth (or riches) with money.' None of the errors of analysis that have been mentioned amount to, or imply, any such confusion. Moreover there is, so far as I know, no proposition to be found in 'mercantilist' writers that cannot be explained—however erroneous it may be—without assuming that they thought that wealth was the same thing as money or bullion or 'treasure,' or that they confused money with what money can buy. We have thus little reason to waste space on a completely uninteresting question. But readers may feel entitled to a comment on what has become a standard topic in the historiography of economics ever since Adam Smith, by his unintelligent criticism of the 'commercial or mercantile system,'[24] set the bad example.

As early as 1549, an anonymous author,[25] setting out to 'declare the means and polices howe to reduce this Realme to a prosperus and floreshing state,' finds it necessary to define in what this flourishing state consists. In his judgment, it consists 'cheifly in being stronge against thinvasion of eneymies [that this comes first is interesting to us from another standpoint, J. A. S.], not molested with cyvile warres, *the people being wealthie* [author's italics] and not oppressid with famyn nor penury of victualles,' the last words being clearly intended to illustrate the 'wealthie.' Yet he wants an export surplus in order to get an import of bullion. Of seventeenth-century authors, Serra, Misselden, Mun ('riches consisteth in the possession of those things which are needful for a civil life'), Child ('many tools or materials'), Cary, Coke, Yarranton, and of course, Barbon, Davenant, and Petty, not to mention the advocates of paper money and of bank schemes, can all be cited in support of the thesis that, whatever their shortcomings may have been and however much they may have overstressed the importance of an increase in 'treasure,' wealth was defined —explicitly or by implication—much as we define it ourselves. A *locus classicus* occurs in a tract signed by Papillon:[26] 'It is true that usually the measure of

---

[24] *Wealth of Nations*, Book IV, ch. 1. Adam Smith's criticism is open to a still more serious indictment. Obviously conscious of the fact that this particular charge cannot be made good, he does not strictly speaking make it, but he insinuates it in such a way that his readers cannot help getting the impression, which has in fact become very general. Excluding writers, German writers especially, who might be called either postmercantilists or neomercantilists, we may date the beginning of the reaction to it by W. Cunningham's article, 'Adam Smith und die Mercantilisten,' *Zeitschrift für die gesamte Staatswissenschaft* (1884).

[25] We have met him before. 'Polices to Reduce . . . ,' *Tudor Economic Documents*, vol. III, p. 313.

[26] Thomas Papillon, *The East-India Trade a Most Profitable Trade to This Kingdom* (1677), quoted from Heckscher, op. cit. II, p. 191. I have not read the book. Professor Viner (op. cit. pp. 17-18) offers a list of quotations to establish his contention that confusion actually existed 'between quantity of money, on the one hand, and degree of wealth, riches, prosperity, gain, profit, poverty, loss, on the other.' In justice both to the writers whom he quoted and to Professor Viner himself, it must be pointed out that he aims at a wider target. Nevertheless it is significant that, as the reader can easily satisfy himself, not a single one of the quotations establishes confusion (or identification) of wealth with money or bullion, though some of them *suggest* the presence of other errors such as we have embodied in our three statements.

Stock or Riches is accounted by Money, but that is rather in imagination than in reality: A man is said to be worth Ten thousand pounds, when possibly he hath not One hundred pounds in ready Money; but his Estate, if he be a Farmer, consists in Land, Corn, or Cattle, and Husbandry Implements . . .'

Yet turns of phrase like Wealth is Money do occur frequently.[27] Sometimes they can be easily disposed of as *façons de parler*. Why, Milles even says that 'Though money were the beames and exchange the very light, yet bullion is the sonne' (quoted by Seligman in his article, 'Bullionists'). Shall we infer that he thought bullion and the sun were the same thing? In other cases, it may be necessary to remember that, while we are dealing with pieces of analysis or attempts at analysis, we are dealing with primitive analysis, the methods of which differ but little from, and on the lower levels readily shade off into, those of the popular mind that still harbored vestiges of the cult of hoards of gold and silver, though the British navy had already ousted the protecting dragon from the place he used to hold. But this is all.

[5. Analytic Progress from the Last Quarter of the Seventeenth Century: Josiah Child to Adam Smith]

Let us return to the main road which, as we already know, rose sharply in the second half, especially the last quarter, of the seventeenth century. Bearing in mind what has been said before about other aspects of the analytic work of those decades, we shall now add what remains to be said about the specifically 'mercantilist' aspect. The work that remains to be noticed under this heading is much more important than that of the preceding decades and consisted largely in a critical revision of the latter—a revision which constitutes the main analytic effort of the mercantilist writers. It seems to me that credit for having given the lead must go to Child.[1] Of other names it will suffice to mention Barbon, Cary, Coke, Davenant, Petty, Pollexfen,[2] Yarranton, and one which I expect some readers will be shocked to find in this list—North, the free trader! [3] The main points to note are these.

---

[27] The reader who wishes for instances can find a little collection in Heckscher, op. cit. II, pp. 186 et seq., which even includes Bodin. Of particular interest is his discussion of *Britannia Languens* (1680), quoted before, because the case of its author differs from the usual case in which such turns of phrase appear occasionally and which we can leave out without changing anything in the argument. He insists again and again that wealth is *not* goods but only treasure and that poverty is nothing but lack of treasure. Even in the face of this, however, it is necessary to insist (a) that his arguments, or some of them, make sense independently of it; (b) that the book is a poor performance not up to the standard of Mun's or Child's; (c) that, though I defer to Professor Heckscher's authority, my own experience of the literature would not justify me in considering it as 'entirely typical' (Professor Heckscher qualifies this, it is true, by adding: 'of a large part of mercantilist literature' and therefore *may* mean what I should not deny); (d) that allowance must be made for the tendency of prevailing schemes of thought to produce freaks—for which thesis the economic literature of the last ten years provides ample verification.

[1] Sir Josiah Child (1630-99) was no systematic writer. His contributions are so scattered over a great many topics that it is easy to miss their combined import. In fact, it has been missed. The additional misfortune of having been a prominent businessman and very rich seems to have sealed his fate as an economist. More than anyone

First, Child—and others about the same time but mainly after him (chief instance, Pollexfen)—drew the consequence of his theory of money, that money, being a commodity like 'wine, oil, tobacco, cloth or stuff' may often be exported as much to the national advantage as any other commodity.[4] This, if properly developed, knocks the bottom out of any position that attaches primary importance to the balance of trade per se. Child did not however proceed to frontal attack, which was, so far as I know, left to Barbon. But he made it inevitable. Similarly, he led up to the two corollaries of his proposition, but failed to state them. The one, that if exportation of gold and silver is nothing to worry about, their importation (the increase in the supply of money) is nothing to exult about, was also developed by Barbon. The other, that the importation of bullion does not add any more to the wealth of a nation than does the importation of raw materials, or even less (observe, however, that this is not in every sense above question), was developed, though somewhat *post festum* (1696) by Cary. The process of analysis that these instances illustrate also did away with the errors discussed before. This may be said to have been accomplished by the end of the seventeenth century. It is true that they were shaken off rather than explicitly renounced, which accounts for the fact that turns of phrase suggestive of them continue to occur even with such

---

else he has been voted 'a special pleader' whose views may be interesting as 'evidence of contemporary business life and opinion,' but have no place in a history of scientific economics. This appraisal may be found in a most typical form in the article 'Child,' in the *Encyclopaedia of the Social Sciences.* The author, Henry Higgs, should really have known better.

[2] John Pollexfen, *A Discourse of Trade, Coyn, and Paper Credit, and of Ways and Means to Gain and Retain Riches* (1697) and *England and East India Inconsistent in their Manufactures* (also 1697). The titles of the relevant publications of the others have all been given before.

[3] Sir Dudley North (1641-91), *Discourses upon Trade* (1691), ed. J. H. Hollander (1907). It is interesting to note how acutely he was conscious of the difference between results of analysis and 'ordinary and vulgar conceits, being meer Husk and Rubbish' (preface); but he was a merchant and, later on, a public servant—no professor.

[4] This must not be confused with the apparently similar argument of Mun's that has been mentioned before. Child's proposition not only went further, but it meant something entirely different. It was not, as it was in the case of Mun's, exclusively motivated by the possibility that such exportation would eventually result in still larger importation. On the other hand, we must guard against a possible misinterpretation: one might read into that passage an anticipation of the principle of gold movements that was sponsored by Ricardo—gold will flow if it is the relatively cheapest commodity. But Child does not envisage the element of commercial advantageousness of gold or silver exports, but only states that the national interest will not suffer if gold and silver are exported. (On Child's monetary theory, see above, ch. 6, sec. 2b and sec. 7a.)

writers as Cary, Davenant, Petty, Yarranton, and later ones, such as Harris, who in substance were quite free from those errors.[5] It is also true that, on what has been referred to as the lower levels, all this lived until it was replaced by 'liberal' slogans—which, on those levels, were of no better grain intellectually.[6]

---

[5] It is amusing to note that the 'mercantilist' writers became so alive to the dangers of overemphasis on money that they began themselves to use the slogan about the identification of wealth and money. Thus, in a pamphlet that has been ascribed to Davenant, Pollexfen was attacked on this ground, although in the *Discourse* he clearly defines wealth in terms of goods and although in *England and East India* he condemns the import trade of the company merely on the ground of the frivolous nature of those imports, which he does not believe were re-exported to a degree to justify Davenant's (and others') argument for that trade. This, whether good or bad economics, has nothing to do with that identification. The same Pollexfen was arraigned by Professor Viner (op. cit. p. 18) for having said that 'gold and silver is the only or most useful treasure of a nation.' But why should this mean more than that gold and silver are 'stores of value,' and best fitted for that role, a statement one can read in the majority of nineteenth-century textbooks on money? This interpretation is entirely adequate to take care of the meaning of his text: of course, as far as that store of value goes, only bullion can make up for loss of bullion.

Pollexfen, serving as he does as one of the standard instances for the views expounded in the text, should be cleared of what I conceive to be unjustified aspersions. We may refer to another point in which he was so unfortunate as to give umbrage to free-trade critics. He 'still' held that it is meaningful to balance trade with each individual country, a standpoint that, to the relief of those critics, Child and Barbon and even Mun had at last abandoned. But provided one does want to regulate and plan—the rationale of wishing to do so is another matter—Pollexfen's opinion is, as has been pointed out in our discussion of Malynes, perfectly sensible as is also his recommendation to set an upper limit to the export of money to India. There is hence no reason whatever to wonder at the survival of this or cognate ideas: anon., *Short Notes and Observations in Point of Trade* (1662) was, from the planner's standpoint, perfectly justified in denouncing the importation of vain and unnecessary commodities; and so was Ralph Maddison (*Englands Looking In and Out*, 1640) in holding that control should be extended to 'every particular trade.'

[6] By way of illustration, both of the statement made in the text and of the rationale of our method of appraising and 'placing' mercantilist (and also other) writers, let me give a late example of the occurrence of what most people will consider typically mercantilist errors. L. A. Muratori, in his *Della pubblica felicità* (1749), ch. XVI, lays it down as the principal maxim that ought to govern economic policy that as little money as possible be let out of the state (*fare, che esca dallo Stato il men Danaro, che si può*) and that as much of it as possible be imported (*e che ve ne s'introduca il più che si può*), a conclusion which was soon (1751) attacked by Galiani. See also A. Graziani, *Le Idee economiche degli scrittori emiliani e romagnoli* (1893). Now I do not try to palliate this by an 'understanding' interpretation. I should agree with every one of Professor Viner's crisp epithets if they were to apply only to cases like this. But I think it essential for a proper grasp of the history of economics to emphasize their low level (which of course is relative to dates). The case derives additional illustrative value from the fact that Muratori was a very eminent man in other fields. Even as an economic historian he stands high. But he did not know how to

[(a) *Concept of the Automatic Mechanism.*] Second, we have seen that the conception of the Automatic Mechanism—the mechanism which, if allowed to work and if conditions are not too much disturbed, may be held to guarantee in the long run an equilibrium relation between the money stocks, price levels, incomes, interest rates, et cetera of different nations [7]—was not entirely outside the range of vision of any of the 'mercantilist' writers one cares to quote: Serra saw much of it, Misselden and Mun, a little, Malynes, nearly the whole of it. The contributions that have just been discussed above, so one might think in retrospect, should have made the full-fledged theory of that mechanism an easy matter of co-ordinating and amplifying restatement. But—as the history of any science again shows: a particularly good instance is afforded by thermodynamics—such definitive formulation is surprisingly difficult to achieve and the first attempts at it are always likely to be failures. None of the authors mentioned did achieve it. North tried. He saw that there is such a mechanism as a result of which every country will draw to itself a 'determinate sum' of money that will just suffice to carry on its economic process (at, and after adjustment to, the appropriate level of prices, a qualification which, however, he does not add). But he went off the rails completely in his attempt to describe it. Locke was more fortunate. He even used the device later on adopted by Hume of trying to describe what will happen, if half of the money in existence in a country be suddenly removed, and realized that this will restrict imports and increase exports, and yet he does not draw the conclusion that to us seems obvious (or seemed so until twenty years ago). But in order to get things into the right historical perspective, it should be realized that this fortress, though it was not completely reduced before the middle of the eighteenth century, was eventually entered, not by means of a new attack from a different side or by a new method of attack, but simply by pressing on through the breach that the 'mercantilist' writers had made. This can be easily shown by a brief survey of subsequent developments, which will at the same time serve the purpose of carrying us not only to the *Wealth of Nations* but beyond it to the threshold of discussion raised by the suspension of specie payments (Bank Restriction, 1797).

The next substantive advance was made by Gervaise.[8] He added the propo-

---

wield the kind of analytic apparatus the evolution of which is the subject of this book, and hence he wrote commonplaces or nonsense when he touched subjects that cannot be successfully treated without it. And this nonsense was not typical of the works of those writers of his time who had command of such analytic apparatus as there was. It would only serve to blur the picture if his views on such subjects were allowed to figure in it.

[7] With regard to this mechanism, see the footnote on the balance of payments (above, sec. 4, n. 6).

[8] I have not mentioned Simon Clement, *A Discourse of the General Notions of Money, Trade, and Exchanges* . . . (1695), whose contribution has been strongly commended by Angell (op. cit. pp. 21 et seq.). But there was little merit in describing the specie-point mechanism that had been perfectly well understood more than a hundred years before. There was, however, merit in Clement's correct description of

sition, never before stated with unmistakable clearness, that an increase in 'credit' (say, banknotes) will increase income and consumption, hence decrease exports and increase imports, and thus produce, just as would an increase in the quantity of the monetary metals, an outflow of these metals that will eventually enforce credit restriction—an important contribution, particularly meritorious in its emphasis upon the 'income approach.' Of course this proposition implies full understanding of the fundamental mechanism we are talking about, since it merely develops a particular consequence of it. But Gervaise's actual account of the automatic mechanism, though superior to any that had been published before, is yet far from satisfactory. It would, however, be sufficient to insert a few passages from Malynes in order to make it so. Successive marksmen, however, came nearer and nearer to hitting the bull's-eye of the old target. Of those who did hit it, the most eminent were Cantillon and Hume.[9] The fact that Hume's essay aroused some opposition testifies to his

---

the sequence of events that devaluation will produce as long as domestic prices do not respond to it: bullion will flow, exports increase, imports decrease. He was not the first to see that, but his is the first compact statement, so far as I know, of the particular piece of mechanism, made with a full sense of its importance. The same claim may perhaps be made for the book as a whole, and if we add it to the contribution of the authors under discussion, it becomes still clearer that *all* the elements for what was to become a 'classical' theory were worked out before 1700.

Isaac Gervaise, *The System or Theory of the Trade of the World. Treating of the Different Kinds of Value. Of the Ballances of Trade. Of Exchange. Of Manufactures. Of Companies. And Shewing the Pernicious Consequences of Credit, and that it Destroys the Purpose of National Trade* (1720). This remarkable little book, the merit of which is only slightly impaired by slips and clumsinesses (for instance, Gervaise lets the precious metals be distributed among countries according to their population, but meets the obvious objection by a fairly satisfactory explanation), has I believe been discovered by the late Professor Foxwell, who called it 'one of the earliest formal systems of political economy, and stating one of the most forcible practical arguments for free trade.' It will be Professor Viner's merit, however, if henceforth these 34 pages take the place in the history of our science that belongs to them (see Viner, op. cit. pp. 79 et seq.).

I take the opportunity to call attention to Professor Viner's section on 'The Self-regulating Mechanism of Specie Distribution' (p. 74), which, the best part of an excellent work, is not only much richer in material than my exposition but also one of the most interesting essays ever written on the fascinating theme of *how a theory struggles into existence*. It is a pity that, in this section as well as in the other parts of his work, he failed to distinguish between progress in analysis and progress toward free-trade opinions, or to put it somewhat differently, between what an author understood of economic processes and what he thought of them. The same common confusion we shall presently encounter again when dealing with the general theory of international trade.

[9] R. Cantillon, *Essai sur la nature du commerce en général*, which, as has been mentioned before, was written (and circulated) about 1730 but did not appear in print until 1755. D. Hume, 'Of the Balance of Trade' in *Political Discourses* (1752), included in *Essays, Moral, Political and Literary* (ed. 1875, vol. 1, pp. 330 et seq.). Comparison with other writers, who may also be said to have hit the bull's-eye, only serves

merit as do the further facts that he added several points which were new, as far as I know, and that, unlike some economists of the nineteenth century, he did not trust the automatic mechanism unconditionally, though he failed to emphasize the frictions and disturbances that may attend its working. Essentially, however, his achievement consisted in shaking off the dust of mistakes from pieces of the 'mercantilist' inheritance and in assembling these pieces into a neat and well-rounded theory.[10] And this is all. Nothing of major importance was added during the rest of the century. In the *Wealth of Nations*, Adam Smith did not advance beyond Hume but rather stayed below him. In fact it is not far from the truth to say that Hume's theory, including his overemphasis on price movements as the vehicle of adjustments, remained substantially unchallenged until the twenties of this century.

[J. A. S. left note: 'please leave rest of page' and added in pencil as a reminder the three names Melon, Dutot, Galiani.]

[(b) *Foundations of a General Theory of International Trade.*] A third point remains to be noticed about the work of our group of writers. Just as they paved the way toward the theory of that automatic mechanism of gold and silver movements, so they also paved the way toward the theory of the automatic mechanism of commodity movements. In other words, they pulled out of that prescientific stage in which the protectionist arguments had *no* theoretical basis, rather than a faulty one, and began to lay the foundations of the general theory of international trade that was to take shape in the last decades of the eighteenth and the first decades of the nineteenth centuries. Logically, though not historically, we may distinguish two steps in their advance.

The first step consisted in the qualification and elaboration of the primitive arguments. They perceived the fact that the immediate and visible advantages that protectionist measures aim at securing are never net advantages or, as we may also put it, that there is to every proposition about those advantages a

---

to make his merit stand out still more clearly. Two may be mentioned: Jacob Vanderlint, who preceded him (*Money Answers all Things*, 1734, p. 15 of the new ed. in J. H. Hollander's reprints) and Joseph Harris (*Essay upon Money and Coins*, 1, who followed him, at least if we go by date of publication, 1757. That these two sound but certainly not first-flight men should have also 'done the trick' seems to strengthen the thesis of the text.

[10] No one who knows anything about the history of science in general will suspect me of a wish to underrate the importance of an achievement of this kind. Moreover, the performance may have been quite original 'subjectively' in the sense in which, e.g., Menger's was (see below, Part IV, ch. 5, sec. 1), all the forerunners notwithstanding. All major discoveries have to be repeated again and again. Finally, there is room for fair difference of opinion concerning the question how far the authors of the seventeenth century had really advanced. In any case, there is no justification for Professor Angell's statement that Hume 'at a single stroke wrecked the balance-of-trade theory' (op. cit. p. 26). This only amounts to repeating an old nineteenth-century error.

counterproposition about ulterior or invisible effects, many of which are in the nature of costs. Such complementary propositions are implied in Cary's argument about the importation of raw materials or Coke's argument about the importation of both raw materials and manufactured goods, or Coke's and Yarranton's argument on cheapness and plenty, or Yarranton's argument about the advantages that accrue to a nation from its neighbors' prosperity, or Barbon's argument—it occurs frequently, but it was not, I think, definitely set on its legs before Barbon—that regulations and restrictions always destroy some element of potential wealth. It is, or was, the common practice of critics to say that by introducing such arguments our authors contradicted or partially recanted their 'mercantilist' views, or that they became 'eclectics.' But whatever may be true from other standpoints, from ours those arguments and the qualifications they implied are simply the inevitable consequence of increasingly successful attempts to see more than one side of the case.

Similar conquests were made by continental writers of the same type. It will in particular not surprise us to learn that the Dutch were in the van of advance. The two outstanding examples are Graswinckel and Pieter de la Court.[11]

Thus, additional and less obvious aspects were gradually revealed, though in a wholly unsystematic manner. But among the disjointed pieces of economic reality that were being unearthed, there was one of sufficient power to coordinate all the others and to support the structure of a comprehensive theory of international trade or even trade in general. Child seems to have been the first to arrive (1668-70) at a clear idea of the explanatory value of the simple fact that commodities tend to seek the most advantageous market. To use the phrase of Davenant, who worked out the idea in the nineties, there are definite 'channels' which, under the stimulus of profit expectations, trade finds of itself; or, to put it still differently, the profit motive supplies a regulatory principle for 'unregulated' business activity, international and national, and produces results which we may like or not but which are determined and not chaotic. Propositions that imply this discovery or even expressly refer to that principle in particular cases occur in the sixteenth century and earlier. It was of course quite familiar to the scholastics. On the other hand, it was not fully developed until Léon Walras. But the mercantilist writers helped to place it in its key position in the theory of international trade.

---

[11] Dirck Graswinckel, *Placaetbook op het stuk van de Leeftocht* (Compilation of regulations concerning foodstuffs, 1651), the second part of which contains a critical analysis of the policies represented by the legislative material compiled in the first. Graswinckel's views on the harm done by prohibiting the exportation of grains, a practice which had become practically universal in the eighteenth century, were not new in 1651—we have encountered similar views in the *Discourse of the Common Weal*, and they cannot have been strikingly novel even then. But Graswinckel had a keener sense of the price mechanisms involved, especially of the function of forestalling. Pieter de la Court, *Interest van Holland* . . . (1662; 2nd ed. under the title: *Aanwysing der heilsame politike Gronden en Maximen van de Republike van Holland en West-Vriesland*, 1669; English trans., *Political Maxims* . . . falsely attributing the work to John de Witt, 1743; I know only the latter), presents mainly an argument for industrial freedom plus moderate duties—comparable and in some respects superior to Coke's of 1670 and 1675—the merit of which consists chiefly in its freedom from errors of reasoning. Both authors would have to be ranked very high in a history of economic thought or policy. Concerning their contributions to analysis, however, it is hardly possible to say more than this.

Neither Child nor Davenant proceeded very far with it. Barbon, however, understood the mechanism sufficiently well to adumbrate the theory of equilibrium in international commodity trade, at least in the form of the proposition—stated without the necessary qualifications—that restrictions on imports will restrict exports to a corresponding amount. Much more than this I cannot find in any seventeenth-century author. In particular very little was made of the argument about territorial division of labor. In its most primitive form it cannot, of course, have ever been unknown to anyone. Armstrong and Hales in the sixteenth century based international trade on the fact that different nations, living under different conditions, produce different commodities, the superfluous parts of which may be exchanged with advantage to all parties concerned. Even North thought of international trade in quite the same spirit as the 'exchange of superfluities,' much as had Grotius (1625). Recognition of the much more interesting fact that this exchange will alter the economic organisms of the trading nations is, to be sure, implied in many practical suggestions, especially on the economic relations between England and Ireland and also in more general considerations of Davenant's (e.g., in his *Essay on the East-India Trade*, 1696), but nobody seems to have realized fully its significance as a starting point of analysis or to have had any inkling of the principle of comparative costs. North in particular did nothing but sum up, incompletely but effectively, the contribution of the 'mercantilist' writings to 1691.

But none of the others were thoroughgoing free traders. North alone was. And to interpreters of the history of economic analysis who were interested in nothing but free trade and knew of no canon of criticism except the distance that separates an author from free trade, this was of course the all-important fact. For them, there is, on the one side, the darkness of 'mercantilist' error and, on the other side, the eternal light of 'liberalism'; the light rose against the darkness and dispelled it so thoroughly that there was nothing left of it except the pious wonder of liberals how anyone could ever have been so benighted. Now this way of looking at the history of that time under the aspect of a sharp antithesis is totally wrong. And it is so essential for a proper understanding of the evolution of our science to grasp this that we must stay for a moment, even at the risk of some repetition, in order to clarify the nature of the confusion from which that view arose.

Even if we were studying the history of political doctrines, it would be necessary to point out that free-trade forces did not simply assemble outside of the mercantilist citadel and storm it—this is only true of the agrarian Tory component, which at that time was strongly antagonistic to big business and protection—but to a much greater extent formed up inside it. This should appeal to Marxists, for the decisive support of English free trade came after all from the same bourgeois class that had previously supported protection. But the advance of analysis that alone interests us here was not a matter of free trade and nascent liberalism at all. It could have occurred without anyone's being converted to free trade and liberalism, and free trade and liberalism could have gained their political victory without any help from that advance. Of this we can satisfy ourselves by the reflection that, for example, none of the old protectionist arguments listed above is affected by the later analysis that, in the hands of liberals, was made to serve free-trade policy. That analysis only established the existence of an 'automatic mechanism.' Knowledge of this mechanism is indeed not irrelevant for practice. When fully developed, it will prevent people from embracing protectionism or free trade for erroneous reasons. But beyond this it is not the master but the servant of the decisions we arrive at. It can serve—and rationalize—protectionist decisions just as well as free-trade decisions, but it does not in itself suffice to enforce either.

It is easy to apply this to the particular case of North. His allegiance to the Tory party had probably much more to do with his free-trade opinions than had his analysis. So far as the latter is concerned, in order to realize that he might have arrived at 'mercantilist' conclusions without any error or inconsistency, we need only suppose that he adopted one of those protectionist arguments or simply that he saw that an individual nation may gain by a well-devised system of protective duties. Therefore, we can discard his free-trade convictions as irrelevant in an appraisal *of his analytic apparatus*. But if we look at the latter, we have no difficulty in recognizing, first, its affinity to Barbon's [12] and, second, the fact that for the rest it is made up of quite old elements: wealth consists of whatever satisfies wants; money is a commodity of which there may be too much as well as too little; there is no sense in prohibiting its exportation or in taking any measures in order to secure an adequate supply of it; sumptuary laws blunt the spurs to trade; and so on. Clearly it is more correct to say that his analytic work grew out of that of the 'mercantilist' than to say that the relation was one of head-on clash.

[(c) *General Tendency toward Freer Trade.*] Let us again follow developments to the publication of the *Wealth of Nations*. It will be convenient to distinguish sharply the development of free-trade *policies* and free-trade *doctrines* from the development of *analysis* that was associated with both.

If due account be taken of all the obstacles that stood in the way, a general tendency toward freer trade is, I think, discernible. In England this tendency had already asserted itself in the growing opposition to the Navigation Acts and other 'mercantilist' measures, for example, in the Committee on Trade of 1668. Much more significant was the assault on the system that the Tories, under Harley and St. John, made in 1713: the eighth and ninth clauses of the peace treaty of Utrecht went a long way toward free trade with France. The assault ended in defeat. The Tories failed to carry those clauses and the subsequent Whig regime (Walpole first, the Pelhams after) kept strictly on the protectionist tack. The governments from Bute's to North's had other worries, but Shelburne and especially the younger Pitt led the way toward fewer and lower duties—the latter's crowning achievement being the commercial treaty with France, 1786. Further progress was checked for nearly thirty years by the revolutionary and Napoleonic wars, after which Pitt's policy was resumed in the twenties of the nineteenth century (by Huskisson). As we can see from this, France moved substantially in step. Only, there were two additional problems: even internal free trade was not achieved until the Revolution, though successive administrations tried to establish it, and the agrarian situation brought to the fore the particular question of free trade in grains, especially free exportation of grains.[13] In the German and Italian states we see at first glance nothing except further development of the 'mercantilist' system. But its rationalization led in many instances to a reduction of the burdens on interterritorial trade, especially in raw materials and semifinished products. In the Netherlands, as we should expect, a much more definite tendency toward freer trade already had asserted itself in the seventeenth century.

---

[12] The only point in which North definitely goes beyond Barbon is the proposition already mentioned on another occasion (see above, ch. 6, sec. 7) viz. that low interest is not the cause but the consequence of increasing wealth. Perhaps his rudimentary theory of gluts should also be mentioned. But it is so very primitive that there is no point in insisting on it.

Doctrine moved more quickly. Free-trade conviction began to spread as part of a general laissez-faire code. With the bourgeois public, the operative impulse was simply surfeit with bureaucratic overadministration, which became so strong that even direct self-interest failed occasionally to counteract it. With the writers, or some of them, a similar impulse took on a philosophic flavor: free trade was increasingly considered as a part of the autonomy of the individual, which was held to imply a 'natural right' to trade as he pleased. This argument, which had been used already by Hugo Grotius and can be followed through the various natural-law groups, including the physiocrats and even the English utilitarians, is of course perfectly devoid of scientific meaning.[14] But it is relevant for us, first, because it was practically always associated with positive statements about economic effects, which do have scientific meaning and must be considered independently of it; second, because we have here (scientifically speaking) an illegitimate influence which blunted the edge of the critical faculty and imparted a bias to the economic reasoning of the best writers.

As we shall see more clearly later on, weaknesses that are not easy to explain in any other way may be traced to this influence, which understandably allied itself with the doctrine of the Invisible Hand, even in the cases of Quesnay and Smith. It counted of course still more in the popular opinions favoring laissez-faire that conquered coffeehouses and salons and foreshadowed the free-trade dogmatism of nineteenth-century liberals, which has not much more to do with scientific insight than had any of the popular dogmas of mercantilism.

---

[13] In England, an export bounty had been introduced in 1689 which naturally played a role in contemporaneous discussion. Otherwise English agrarian policy did not clash much with the general tendency described above until 1815.

[14] I hope I have made it quite clear before that my defense of the natural-law concept as an instrument of analysis does not cover its use as a means of deriving imperatives of the type of the *droits de l'homme*.

Analytic progress, however, was slow. The controversies that arose about political issues, which happened to attract public attention, proved surprisingly sterile in this respect. The one raised by the French grain policy,[15] for instance, though it engaged the interest of some of the brightest stars of economic analysis, François Quesnay included, did not produce any results that we should have to notice.[16] Still there was some advance, though advance that led to new error as well as to new truth.

---

[15] We may notice another. When the freer trade clauses of the peace treaty of Utrecht became known, the protectionists flew to arms. Among other things, a short-lived periodical was founded, *The British Merchant* (republ. 1743), the contributors to which throw an interesting light on the state of protectionist opinion. Among them, Joshua Gee should be mentioned in particular. He also wrote other protectionist tracts, e.g. *The Trade and Navigation of Great Britain considered* (1729), and his protectionism mainly turns upon the employment argument. On the whole, the performances of Gee and of the other contributors were by no means discreditable and, intended as they were for popular consumption on an issue of the day, may well be offered in refutation of the common belief that eighteenth-century 'mercantilism' was just a heap of nonsense. But as far as I can see, there was nothing in them to interest us here. The Tory counterblast was *Mercator, or Commerce Retrieved*, which appeared three times a week from May 1713 to July 1714 and was more of a one-man show. That man was Daniel Defoe of *Robinson Crusoe* fame, a most brilliant and prolific writer. But even his most ambitious efforts in our field remained in the sphere of economic journalism. In particular, his case for those clauses of the Treaty of Utrecht did not contribute anything new to economic analysis, though they rank high in the history of free- or freer-trade opinion. The reader who takes the trouble to peruse some of his writings (e.g. his *General History of Trade*, 1713) may well think that I am being unjust to him, especially if he recalls my comments upon Yarranton. But merit in such matters is to a large extent a matter of dates.

I take this opportunity to mention a somewhat later writer, Malachy Postlethwayt, but only to give an instance of the interesting phenomenon of the survival of names associated with substandard performance. The sole reason that I can see why this name should still be familiar to every student preparing for a course examination in the history of economic thought is a certain reputation he made in his own time by his *Universal Dictionary of Trade and Commerce* (1751-55), which was largely a compilation from unacknowledged sources. His other writings, mainly on the South African trade, are narrow and pedestrian, though not devoid of a certain crude common sense. His *Great Britain's true System* . . . (1757), which proves that he was intelligent enough to see the importance of Cantillon's book, contains a passage that interprets interest as a payment to hoarders by those who stand in need of it, i.e. as a payment necessary in order to overcome people's reluctance to part with cash. This reads like a clumsy version of Lord Keynes's own-rate theory of interest. To put him in a representative position as has recently been done by Fay . . . [note unfinished].

[16] That discussion has, however, some indirect importance for us owing to the general stimulus it gave to the interest in economic analysis, even though it did not add much to it directly. This is why it will have to be mentioned again. At the

[(d) *Benefits from Territorial Division of Labor.*] The one major accomplishment that I can see consisted in a technically superior formulation of the benefits from territorial division of labor that went some way toward anticipating the most important element in the nineteenth-century theory of international values. It stands to the credit of two English authors to whom we shall confine ourselves, though others could also be cited. An anonymous writer, in 1701, published a tract entitled *Considerations on the East-India*

---

moment let us note that all the authors to be mentioned were, in this matter, anticipated by Graswinckel, 1651 (if not in the *Discourse of the Common Weal,* 1549) and more immediately by Boisguillebert. After Boisguillebert there was a lull. It seems that the discussion was started afresh by Claude Dupin (*Oeconomiques,* 1745, of which the part entitled *Mémoire sur les bleds* was republ. separately in 1748), who presented once more the argument for internal free trade in grains. C. J. Herbert followed with his *Essai sur la police générale des grains* (1753). The fact that he still retained an export duty (of the English sliding-scale type) is immaterial here; it is more relevant that the argument about the adequacy of the *normal* supply that will be automatically forthcoming is fully developed by him, though without anything amounting to theoretical proof. Quesnay followed in an essay that will be mentioned later, and so did others, especially after the declaration of 1763 and the edict of 1764 which established free exportation. Galiani's spirited criticism of the dogmatic beliefs that were being developed (*Dialogues sur le commerce des blés,* 1770) is particularly worthy of notice.

These *Dialogues* grew out of the corresponding discussion among Italian economists, which began later and lasted longer and is really more interesting than the French one—though participants in the latter may claim priority as to such fundamental ideas as were involved—because the particular patterns of the situation in the Italian states, especially in the Neapolitan Kingdom, suggested both factual studies of considerable interest and arguments on particular points that were absent in the literature of the more fortunate nations. Since, however, it is impossible to go into these results, none of which, so far as I know, were of major importance to the development of the economic apparatus, it must suffice to mention some of the more significant of those performances which, as pointed out in the text, soon began to indicate the influence of the *Wealth of Nations.* For instance, Domenico Cantalupo published in 1783 a tract on free trade in grains (republ. in Custodi's *Scrittori classici Italiani*), in which he analyzed grain policy since 1400 and wielded the modest analytic apparatus at his command effectively and judiciously. Another Neapolitan noble, Domenico Caraccioli, followed him in 1785, interpreting his observations during a famine in Sicily (republ. in the same collection). Biffi Tolomei, in his *Confronto della ricchezza dei paesi che godono libertá nel commercio frumentario* (1795), attempted a factual proof of the importance of free trade in grains for the wealth of a country that is methodologically not without interest. There is appended to this book a memorandum entitled *Riflessioni sopra le sussistenze* by Saverio Scrofani, an out-and-out free trader of the physiocrat type whose other works need not concern us here. All these authors were, so far as the principle of free exportation of grains is concerned, anticipated by Verri, *Memorie storiche sull' economia pubblica dello stato di Milano* (written, 1768; publ. posthumously 1797) and *Riflessioni sulle leggi vincolanti, principalmente nel commercio de' grani* (written 1769, printed 1796). As an example of the success—for it was success and not eclectic weakness—with which conflicting, yet ineluctable, considerations were combined to fit Italian situations, I will mention Ferdinando Paoletti who, though

Trade,[17] in which he treated international trade as a method of acquiring goods with an amount of labor smaller than would be necessary to produce them at home. He does not seem to have been aware of the relation of this to the principle of comparative cost, but even so we have here a predecessor of Ricardo, though possibly a quite uninfluential one.

Now producing instead of a commodity A for domestic consumption, another commodity B, the export of which will fetch in commodity A at more advantageous terms, is obviously a matter of allocation of productive resources. From this angle the problem was considered by Gervaise, who inferred like Marshall[18] that tariffs, spelling as they do interference with the most advantageous allocation, must net a disadvantage to the nation as a whole, however great the immediately visible advantage to the protected industries might be. It has been mentioned that Gervaise's tract has but 34 pages and if, on the strength of this, we give him credit for what he might have had to say in ten times as many, then this proposition must indeed be looked upon as a considerable contribution to the apparatus of economic theory. It may, in fact, be said to give, in the guise of an application, one of the earliest glimpses of the theory of general equilibrium.

But there was hardly anything else. Hume, in spite of the many wise things he had to say in his essays on commerce, on the jealousy of trade, and on the balance of trade,[19] hardly carried this part of our subject any further. Neither did Adam Smith, who seems to have believed that under free trade all goods would be produced where their absolute costs in terms of labor are lowest, though he no doubt co-ordinated, rounded off, emphasized, and illustrated. In fact there is nothing of importance to report for the rest of the century in spite of the mounting flood of popular literature, most of which was of free-trade or freer-trade complexion and strongly influenced the *Wealth of Nations*.[20] And even that advance in the analysis of territorial specialization was

---

also one of the group of Italian physiocrats, inserted into his scheme of things agrarian protection (*Pensieri sopra l'agricoltura*, 1769; I only know the part included in the Custodi collection) and export bounties on goods not of prime necessity (*Veri mezzi di render felici le società*, 1772)—a sort of rudimentary Agricultural Adjustment Program that is not without interest to the theorist. It would be quite wrong to think that general principles of thought or action separate us from an author like Paoletti. What does separate us from him is exclusively our statistical and theoretical technique.

[17] [In J. R. McCulloch, ed., *A Select Collection of Early English Tracts on Commerce*, 1856.]

[18] *Official Papers*, published for the Royal Economic Society (1926), p. 391.

[19] Compare, however, the chapter on Hume in E. A. J. Johnson, *Predecessors of Adam Smith* (1937).

[20] The opinions on foreign trade of some important writers, such as the physiocrats or certain authors of comprehensive systems, may be of interest without involving 'contributions.' So far as necessary these will be mentioned or have been mentioned in connection with the works in which they occur. It is, however, convenient to supplement the exposition in the text in two ways. First, it is worth while to point out that in the twenty-five years or so preceding the publication of the *Wealth of Nations*, the majority of competent economists had reached what amounted to substantial agree-

not an unmixed gain. Both the anonymous author and Gervaise were much too ready to arrive at conclusions agreeable to their free-trade opinions [21] and

---

ment, the physiocrats and the writers directly influenced by them being the most important group in the minority. Representative of this *communis opinio* at its best were Josiah Tucker and Sir James Steuart in England, Justi and Sonnenfels in Germany, Beccaria, Genovesi, Verri, and Palmieri in Italy, and Forbonnais in France. Briefly, since they agreed in accepting public regulation as a normal, in fact inevitable, feature of the economic process, protectionism followed simply as a special case. But the mercantilist emphasis upon the balance of trade was reduced to small proportions, partly in consequence of valuable critical work (e.g. Verri in his *Meditazioni*, 1771, and Carli in his *Breve ragionamento sopra i bilanci economici delle nazioni*, 1770, which made short work of the idea that national wealth can be measured by exports). Moreover, protectionism in their hands became a much more delicate instrument than it had been, one of the consequences of which was the emphasis upon moderate rates, which modern eyes can hardly distinguish from no duties at all: Forbonnais suggested 15 per cent *ad valorem* and Justi 10 per cent. There was a tendency, however, widespread and inspired by very old practice, to believe in differentiating duties upon imports in inverse proportion to their distance from finished consumers' goods (Tucker, Verri)—a principle that proved a hardy growth and is often met with in the nineteenth century. Finally, though (as the uncritical acceptance of this rule by many writers is in itself sufficient to show) they frequently committed the kind of error that results from inadequate technique and places too much reliance on *prima facie* common sense, they rarely went wrong in matters of fundamental *analytic* principle.

Again, we shall readily understand why those critics who accepted the free-trade creed should have been unable to see anything in this except inconsistency or, at best, an uninteresting eclecticism characteristic of a transitional stage between old error and new truth. But from any other standpoint, there was no inconsistency (in the sense of logical incompatibility) in that quasi-common opinion, which not only reflected progress of analysis but also, as will be more generally re-emphasized in the text, might have been a better starting point for further research than was the narrow dogmatism of the free-trade doctrine that replaced it.

Second, by way of illustrating the preceding sentence, let us consider a single instance from a very large class of propositions. In his *Ways and Means . . .* (1757), Massie argues (as others had before him) that Port should be less heavily taxed than French wines, on grounds that suggest the following proposition. If a country, A, trades with countries B and C, and B's purchases of A's products are more elastic *with respect to the revenue that B draws from its sales to* A than are C's purchases of A's products with respect to C's revenue from C's sales to A, then it will benefit country A to treat B's products better than C's. Never mind how far this is true. True or false, this proposition is at least interesting, and its discussion is much more likely to enrich our understanding of international trade and our analytic apparatus in general than are any number of free trade platitudes, however meritorious an attitude the latter may reveal and however conducive to wise, humane, peaceful, and so on policy they may be. Several additional instances could be adduced from Massie alone, who excelled in this eminently useful kind of analysis, also in fields other than that of international trade (see e.g. his *Observations on the New Cyder-Tax, so far as the same may affect our Woollen Manufacturies, Newfoundland Fisheries . . .* 1764).

[21] On Professor Viner's authority (op. cit. p. 92), it may be stated that besides those two and North, there were, before 1776, only two other English free traders (William

in so doing associated their achievement with errors of reasoning that were to become typical in the free-trade literature of the nineteenth century. Gervaise did not realize that his theorem about the allocation of resources cannot tell against any of those protectionist arguments, such as the infant-industry or the underemployment argument, which visualize conditions to which that theorem does not apply. By neglecting this Gervaise moved away from many valuable truths that had been unearthed by the mercantilist writers and, like North, adopted an attitude that, though permissible in pure theory, was bound to produce error when uncritically adhered to. The case of the anonymous author is still worse. He leans heavily on the argument that, *because* international trade consists of voluntary transactions, which therefore must necessarily be to the advantage of both contracting parties, nothing but advantage to the nation as a whole can result from it. North had also reasoned like this. And Adam Smith, after pointing *more suo* to an obvious fact, namely, that every individual will turn to that occupation for which he feels himself best adapted, goes on to declare that 'what is prudence in the conduct of every private family, can scarce be folly in that of a great kingdom.' From the standpoint of analytic technique, this was quite as bad as anything that can be charged to the debit of the 'mercantilist' account. However, the error involved will have to be discussed fully later on.

We have seen that, as far at least as economic analysis is concerned, there need not have been any spectacular break between 'mercantilists' and 'liberals.' Without any prejudice to their political ideals or interests, economists of the latter persuasion might have succeeded the economists of the former persuasion at the analytic task, much as one team of workmen succeeds another in order to carry on the job. To some extent this is what happened. But to the extent to which it did not happen, there was not only scrapping of outmoded error but also needless waste—comparable to the waste that would result if successive teams of workmen smashed the products of their predecessors, whenever they disliked the latter's politics. If Smith and his followers had refined and developed the 'mercantilist' propositions instead of throwing them away, a much truer and much richer theory of international economic relations could have been developed by 1848—one that could not have been compromised by one set of people and treated with contempt by another.

Paterson, the founder of the Bank of England, *Writings* edited with biography by Saxe Bannister, 2nd ed. 1859; and George Whatley, *Reflections on Coin in General*, 1762, reprinted in revised form as an appendix to the 2nd ed. of his *Principles of Trade*, 1774, the only one I know) and one author who came near to being a free trader (J. Jocelyn, *An Essay on Money and Bullion*, publ. 1718 but dated 1717). In a history of free-trade doctrine they are all of them entitled to prominent places. But Paterson's advocacy of free trade moved on a popular level and Whatley and Jocelyn, though not without merit, did not, so far as I can see, add anything to what had been said before them.

PART III

FROM 1790 TO 1870

CHAPTER 1

Introduction and Plan

1. COVERAGE 379
2. PARAPHERNALIA 380
3. PLAN OF THE PART 383
4. CONCERNING THE MARXIST SYSTEM 383

1. COVERAGE

THIS PART is to cover the history of economic analysis from the 1790's to the end of the 1860's or the beginning of the 1870's. For a decade or two after the publication of the *Wealth of Nations* there is little to report *as far as analytic work is concerned,* and most of what there is has been fitted into Part II. I can see no point in insisting on a particular year, but if we did so insist, we might start a new period of analytic activity with Malthus' first *Essay on Population* (1798). Publication of the first volume of Marx's *Das Kapital* (1867), of Jevons' *Theory* (1871), of Menger's *Grundsätze* (1871), and the foundation of the Verein für Sozialpolitik (1872) are some of the events that clearly mark the advent of another period.

Periodizing, as we know, is a necessary evil. There is first an objection of principle to it that applies independently of the particular way in which a writer periodizes: historical developments are always continuous and they can never be cut into pieces without arbitrariness and loss. By refusing to date by years, we do not solve the problem but only mitigate the consequences of our inability to solve it. Second, our particular way of periodizing, dictated as it is by our concentrating on the history of economic analysis, will inevitably fail to satisfy those who are interested in something else. And, third, even from the standpoint of fellow students of the history of analysis, there are well-founded objections to a method that puts A. Smith near the end of the preceding period instead of at the beginning of the one that might be said to have been dominated by his influence. Our recognition of all this will show in many ways, for example, in the fact that we do not deal in this Part with all the authors who belong in it chronologically—the most important instance is Cournot—and that we include some who do not belong in it chronologically—an instance is Cairnes. But I hold, nevertheless, that our periodization brings out essential truth. This will be for the reader to judge. But we may mention at once two facts that go some way toward justifying our procedure. First, many historians before us have felt that this period formed a real unit. The feeling has expressed itself in a distinctive name: it was called the 'classic' period of economics—in a sense quite different from that in which the term is used in this book.[1] It retained this label until, at a time when the word

---

[1] Let me recall that whenever the term is used in this different sense in this book, it is put into quotes in order to prevent confusion. There are three meanings to be kept

'classic' had lost its eulogistic connotation and was *beginning to stand for* 'obsolete.' Lord Keynes used the word in order to denote the teaching of A. Marshall and his immediate followers (or simply, pre-Keynesian economics). Second and more important, the time between the 1790's and the end of the 1860's does answer our criteria of a period: there was, first, fresh activity that struggled hopefully with the deadwood; then things settled down and there emerged a typical classic situation in our sense, summed up in the typically classic achievement—again, in our sense of the term—of J. S. Mill, who underlined the fact by his attitude of speaking from the vantage ground of established truth and by the naïve confidence he placed in the durability of this established truth. Then followed stagnation—a state that was universally felt to be one of maturity of the science, if not one of decay; a state in which 'those who knew' were substantially in agreement; a state in which, 'the great work having being done,' most people thought that, barring minor points, only elaboration and application remained to be done.

2. PARAPHERNALIA

Something that is very like envy comes in to spoil the smile with which we are apt to greet the numerous passages in the writings of this period that breathe immense complacency. Economists, or most of them, were evidently as pleased with the results of their handiwork as some of them were to be again in the 1930's. We shall make an effort later on to understand that happy state of mind in which economists saw a solid house where they had erected nothing better than a flimsy shack:[1] we still underrate pre-Smithian achievement; we still overrate the achievement of the 'classics.'

The conditions under which this work was carried on may be briefly characterized as follows. I hesitate to say that professional economics definitively established itself during this period. It certainly cannot be said that economics as a profession established itself, for the study of economic phenomena was not yet a full-time job and few people were economists and nothing else: many were businessmen, or public servants, or journalists, and even the academic teachers of economics, in many if not in most cases, also taught cognate —or even completely different—subjects. Nevertheless, we have a right to speak of a rapid process of professionalization that went on during that period: from the first, economics had established its claim to a definite field of research; it had become a definite specialty; it used definite methods; its results gained in definiteness; and economists, even though fractional personalities, recognized one another, and were recognized by the public, more definitely than before. New political economy societies were founded; new journals, new dic-

---

distinct: the old meaning in which 'classic' denotes the economic literature of the period under discussion plus A. Smith; Lord Keynes's meaning; and our own. [J. A. S. intended to treat this subject more fully in the unfinished Part I. See also Part IV, ch. 1.]

[1] See, especially, the often ridiculed passage on value theory in Mill's *Principles*, Book III, ch. 1, §2.

tionaries, and new bibliographies appeared—all of which, however, meant only continuation of previous practice.[2] The study of the history of economic thought made a vigorous start[3] and there was, of course, a rising tide of textbooks, a few of which we shall mention as occasion arises.

---

[2] Of the societies, the Political Economy Club of London (1821) was the most important; of the journals, the French *Journal des économistes* (1842); of the dictionaries, the French *Dictionnaire de l'économie politique* (Coquelin et Guillaumin, 1853-4). It is interesting to note that no journal exclusively devoted to scientific economics was founded in England until 1890. In part, however, this was owing to the existence of those excellent serious magazines, such as the *Edinburgh Review*, the *Quarterly Review*, the *Westminster Review*, which accepted even strictly professional stuff—a great compliment to the period's reading public. Beyond using a very limited number of articles that I found quoted in the 'professional' literature, I have not examined the contents of these periodicals—a serious lacuna in my work. I have examined the *Dictionnaire* but only perfunctorily.

[3] Historical references on individual points of doctrine date far back, of course. In the eighteenth century appeared also several bibliographies but no histories that I know of, except a few on the physiocrat school by Dupont and others. From the beginning of the nineteenth century, however, an increasing interest in doctrinal history manifested itself. The sketches of McCulloch (1824-5) and J. B. Say (1829; in the 6th vol. of the *Cours complet*) are the only publications of this kind that need be mentioned here for the time until 1837 when the first edition of J. A. Blanqui's *Histoire de l'économie politique* . . . (with a *bibliographie raisonnée*) appeared. A number of others, some of them confined to individual countries, followed to 1870. By 1858 this literature had grown sufficiently to induce Robert von Mohl (1799-1875) to insert in the third volume of his *Geschichte und Literatur der Staatswissenschaften* (1855-8) a chapter on Writings on the History of Political Economy. I shall mention only: (1) McCulloch's *Literature of Political Economy* (1845); (2) Ferrara's prefaces to *Biblioteca dell' Economista* (in 1850-68, Francesco Ferrara edited two series of Italian translations of foreign works which he prefaced by elaborate analyses that form the bulk of his theoretical contribution and really sum up to a history of economics; most of them were separately published in 1889 90); (3) Roscher (a great part of W. Roscher's work was in the field of doctrinal history. Within the period he wrote his *Zur Geschichte der englischen Volkswirthschaftslehre im sechzehnten und siebzehnten Jahrhundert*, 1851-52; *Über die Ein- und Durchführung des Adam Smith'schen Systems in Deutschland*, 1867; and he poured out his enthusiasm about Oresmius [see above, Part II, ch. 2] in *Ein grosser Nationalökonom des vierzehnten Jahrhunderts*, 1863; we add, immediately, his later *Geschichte der Nationalökonomik in Deutschland*, 1874, the fruit of enormous labor); (4) Manuel Colmeiro's *Historia de la economia politica en España* (1863), which does not strictly belong here but, together with his *Biblioteca* (1880), still forms the best starting point for a study of Spanish economics. I acknowledge the help derived from Dr. E. Schams's excellent study, 'Die Anfänge lehrgeschichtlicher Betrachtungsweise in der Nationalökonomie,' *Zeitschrift für Nationalökonomie* (September 1931), and his and Professor O. Morgenstern's 'Eine Bibliographie der allgemeinen Lehrgeschichten der Nationalökonomie,' ibid. (March 1933), which, however, excludes articles and also all work in doctrinal history that was incidental to theoretical investigations of primarily nonhistorical scope. Dr. Schams dates the beginning of a 'scientific' epoch of doctrinal historiography from E. K. Dühring's (see below, ch. 4) *Kritische Geschichte der Nationalökonomie und des Socialismus* (1871).

Research was largely financed by the research workers themselves: Tooke's achievement, for example, was possible only because he was a wealthy man; in some cases, of course, the proceeds from commercial publication of results proved adequate. Teaching was wholly inadequate, however. Even in those countries where there had been provision for regular lectures before, such as Germany, Italy, Spain, and Scotland, the intention was to provide a complement to other lines of study—law, for instance, or philosophy—rather than an independently organized curriculum of training in economics per se. In the United States a professorship of Moral Philosophy and Political Economy was founded at Columbia in 1818, and a professor of chemistry was commissioned to lecture on economics at South Carolina College in 1824. Teaching of sorts had, however, been done before that at various places by people of the most varied qualifications. In England, very few professorships or lectureships antedate the subsequent period. The one at Oxford was founded in 1825—the first incumbent was Senior—the one at University College, London, in 1828—the first incumbent was McCulloch—the one at Dublin in 1832—the first incumbent was Longfield—and there was a chair of history, commerce, and finance at the East India College in Haileybury to which Malthus was appointed in 1805.[4] But stipends and other conditions of tenure amply prove that founders and administrations did not even wish that people should hold appointments for long, let alone that they should make them their life jobs. In England a National Association for the Promotion of Social Science was founded in 1857 in order to remedy this state of things, but it took decades to achieve perceptible success.

This must be taken into account in any appraisal of the period's performance and still more in any appraisal of an individual's performance. On another occasion I shall have to emphasize that funds and chairs are not everything, but here I have to emphasize that neither are they nothing. Under those circumstances, men of brilliant ability and wide culture touched upon our field so lightly that all their abilities and acquirements did not prevent them from making insignificant economists—which is why, in our field and for that period, a given appraisal of the performance does not necessarily imply appraisal of the man.[5]

Barring a few lonely peaks abroad, England easily comes out first in that period's performance. In fact, that period was the specifically English period in the history of our science. The unrivaled prestige that English economists then enjoyed was only in part due to the glory that was irrationally reflected upon them from the economic success of their country. Mainly, that prestige was due to the quality of the work done by them, not only by a small number of masters, but also by a large number of able writers, who were not in the front rank but whose combined efforts amounted to a great deal.

---

[4] In France, some provision was made, temporarily, in the 1790's and then again after the Napoleonic Wars, but only in Paris (see below, ch. 4, sec. 4).

[5] If the reader will look up a biography of such a man as Pellegrino Rossi, he will immediately realize the force of this remark. But even in such a case as that of J. S. Mill, it is obvious that much of what strikes us as unsatisfactory in his *Principles* is easily accounted for by the fact that this work was largely written in an office with Mill's mind disturbed by the calls of current duties.

3. Plan of the Part

We are going to change our method of presentation. In Part II we had not only to cover a vast span of years but also to contend with the difficulty that there was no generally accepted system to describe. Strictly speaking, no such system existed in the period covered by Part III. But there was something that was almost though not quite as good. That is to say, the great majority of the people who, as we have put it, recognized one another as economists agreed sufficiently about the fundamentals of subject matter, method, and results to make it possible to systematize their contributions, although they disagreed—individually or groupwise—on practically every individual problem within that frame of fundamentals. There was even more of common ground and, as between successive decades, of continuity than the individual writers would have been prepared to admit. For, then as now, most economists were apt to stress differences more than agreements, though there were important exceptions to this, the most important being J. S. Mill. It is true that there were many dissentients *toto coelo*, men who condemned the growing quasi-system of 'classical' economics root and branch. But most of these do not meet our test of analytic competence. And others objected on nonanalytic, that is, mainly on political, moral, or cultural grounds, so that their objections are not necessarily [1] relevant for us, even where we sympathize with them.

Availing ourselves of these facts, we shall be able to do in this Part what we were not able to do in Part II, namely, after having recalled the salient features of the political and intellectual scenery (Chapters 2 and 3), to draw a picture of analytic *developments* with reference to a cross section. This cross section will be represented (in Chapter 5) by J. S. Mill's *Principles*. But in order to simplify matters, we shall relieve Chapter 5 of some of its burden, by introducing ourselves to the most important individuals and groups beforehand (Chapter 4) and by reserving the details of pure theory and of money, as much as possible, for two separate chapters (6 and 7). Chapter 7 will also take care of the little that must be said on banking and cycles.

4. Concerning the Marxist System

Our plan is simple and works well in all cases save one: the case of the Marxist system. The difficulty is not, as might be supposed, that Marxist economics stands aloof in splendid isolation and is incommensurable with the rest of the work to be discussed. We shall see, on the contrary, that it is part and parcel of that period's general economics, which is precisely why it must be fitted in here. I was not thinking of Marx when I spoke of dissentients

---

[1] The reader will understand, of course, that a moral objection may constitute a motive for finding factual or logical objections that *are* relevant for us.

toto cælo in the preceding section, and he can and will be treated in this book exactly as are other economists.[1] Nor does the difficulty arise from the fact that he was also a sociologist. For his sociology can be fitted into its appropriate place just as well as can his economics. The difficulty is that in Marx's case we lose something that is essential to understanding him when we cut up his system into component propositions and assign separate niches to each, as our mode of procedure requires. To some extent this is so with every author: the whole is always more than the sum of the parts. But it is only in Marx's case that the loss we suffer by neglecting this [2] is of vital importance, because the totality of his vision, as a totality, asserts its right in every detail and is precisely the source of the intellectual fascination experienced by everyone, friend as well as foe, who makes a study of him. The way in which I propose to meet this difficulty cannot be satisfactory to the orthodox Marxist for whom Marx is the central sun of social science. Nor can it be satisfactory to him who wants artistic pictures of individual thinkers. But it is perfectly satisfactory for every reader who wants the picture of the evolution of technical economics that this book is intended to present. We recognize fully, but do not mean to duplicate, the distinct task of Marxology. We shall not disturb our plan. We shall take Marx's work to pieces and shall use, with strict economy, only what is relevant to our purpose, in the places indicated by our purpose. But we shall use the rest of this section in order to comment on the whole.

1. Marx figures in this book only as a sociologist and an economist. Of course, that creed-creating prophet was much more than this. And his creed-creating activity, on the one hand, and his policy-shaping and agitatorial activity, on the other hand, are inextricably interwoven with his analytic activity. So much is this the case that the question arises whether he can be called an analytic worker at all. This question may be answered in the negative from two very different standpoints. The orthodox Marxist, for whom the prophet's every word is eternal truth and for whom dissent spells not only error but sin, will return a negative answer, but in this particular sense: on Marx's Hegelian eminence, acting and reasoning, reality and thought, become identical; analysis cannot, on that level, be divorced from practice; therefore, if we do call Marx's thought analytic, we ought to add at once that it was analytic in a sense that

---

[1] Since this point is both very important and likely to cause surprise to some readers, I wish, besides referring them to what they will read in subsequent chapters, to state at once that this surprise is entirely due to the atmosphere of prophetic wrath in which Marx presented his economic analysis and which, to layman and philosopher, makes it look like something entirely different from any other. It is true, in addition, that the Anglo-American professional literature, both in this and the next period, treated him as an outsider. But in that literature other foreign economists of first rank fared no better in this respect.

[2] We never neglect this *quite*. In all the more important cases, economists are 'introduced' to the reader and these introductions give us the opportunity to look at personal performances as a whole. But I cannot go too far in this, for theorems and not persons are the heroes of our story.

differs essentially from the usual one; hence, his work is not analytic in the usual sense, and the author of this book, congenitally incapable of doing justice to it, ought to keep his unholy hands off it. Some anti-Marxists would agree in the result, though they might formulate it differently by advising me to keep my hands off the unholy thing: for them, Marx's work is a series of essentially unscientific diatribes, penned by a man congenitally unable to see a fact or to reason straight.

My answer to our question is, however, in the affirmative. The warrant for this affirmative answer is in the proposition that the bulk of Marx's work *is* analytic by virtue of its logical nature, for it consists in statements of relations between social facts. For instance, the proposition that a government is essentially an executive committee of the bourgeois class may be entirely wrong; but it embodies a piece of analysis in our sense, acceptance or refutation of which is subject to the ordinary rules of scientific procedure. It would be absurd indeed to describe the *Communist Manifesto,* in which this proposition occurs, as a publication of scientific character or to accept it as a statement of scientific truth. It is not less absurd to deny that, even in Marx's most scientific work, his analysis was distorted not only by the influence of practical purposes, not only by the influence of passionate value judgments, but also by ideological delusion.[3] Finally, it would be absurd to deny the difficulty that in some cases rises to impossibility of disentangling his analysis from its ideological element. But ideologically distorted analysis is still analysis. It may even yield elements of truth. To sum up: we shall not chant O *Altitudo* each time Marx's name turns up in the following pages; but neither do we put him out of court *a limine;* we simply recognize him as a sociological and economic analyst whose propositions (theories) have the same methodological meaning and standing and have to be interpreted according to the same criteria as have the propositions of every other sociological and economic analyst; we do not recognize any mystic halo.[4]

---

[3] On the difference between these three kinds of distortion, see above, Part I.

[4] Let me repeat this: due account being taken of differences in definitions and in degree of abstraction, every Marxist proposition is to carry the meaning which it would carry if penned by, say, Ricardo. This formulation takes care of a claim often, and sometimes justly, made by Marxists, viz. that critics (and even followers) of Marx are likely to miss his meaning by failing to attend to the facts that (1) Marx's terminology differs from that of other economists (the word Value e.g., simply means different things with Marx and J. S. Mill); and (2) that he reasons, in different parts of his work, on widely differing levels of abstraction. At the same time, that formulation spells refusal to admit another claim, noticed above, that is sometimes made by Marxists and is implied in their answer to the question concerning the logical nature of Marx's analysis, namely, the claim that Marxist propositions have, as it were, an astral body that is exempt from the ordinary rules of scientific procedure. Our reply to this is: Marx reasons about the empirical world by the methods of empirical analysis; hence his propositions—as every Marxist who discusses criticisms at all, recognizes by implication—have the usual empirical meaning or none. On the influence on him of Hegelian philosophy, see below, ch. 3, sec. 1b.

11. Since Marx counts for us only as far as he was a 'scientific' sociologist and economist, we need not consider any aspects of his career, activities, or personal character that are not relevant to his 'scientific' work. I wish to disclaim any intention to 'size him up' as a man, and this also applies to his friend and faithful ally, Engels. Some facts, however, are necessary in order to see the work of each in its proper light. They are presented in the footnote below.[5] Let us underline a few of them. First, nobody will understand Marx and

---

[5] Karl Heinrich Marx (1818-83) was the product of a thoroughly bourgeois environment that failed to provide economic independence, and of a thoroughly bourgeois education that made him (as it makes so many) an intellectual, a radical, and a scholar—the radicalism being of the bourgeois brand of his time and the scholarship being of the historico-philosophical, as distinguished from the mathematico-physical, type. As much by choice as by necessity, he took to journalism rather than to the academic career and in 1843 went to Paris, where he met Engels and economics (which he had touched only peripherically before) and where he made his position definitively socialist. In 1849, he settled in London for good and, for such a voracious reader, this is almost equivalent to saying that he settled in the British Museum library for good. Active revolutionism—such as he had practiced in 1848 in Germany—was finished, and his research work was for the rest of his life interfered with only by the necessity of earning his bread (in part by journalistic work), by his activity in the First International (1864-72), and later on also by failing health. The standard biography is still F. Mehring's (1918). Though in some respects less marred by narrow prejudice than are other works of this writer and in general commendable, it calls for a protest on behalf of Marx in one respect: it entirely failed to do justice to the scientific element in Marx's work. We ourselves may find in his works abundant proofs of ideological bias, but Mehring goes too far when he credits Marx with *nothing* but an intention to formulate proletarian ideology (of course he means to be complimentary).

Friedrich Engels (1820-95) interspersed a fairly successful business career with revolutionary activities until 1869, when he retired from business in order to serve the cause of Marxist socialism for the rest of his life. Among other things he became the warden of Marx's literary remains after the latter's death and, in addition, something of an oracle and elder statesman (hence the object of attack by a younger generation) to the German Social Democratic party. His self-effacing loyalty cannot but command our highest respect. Throughout he aspired only to be the faithful henchman and mouthpiece of the Lord Marx. It is therefore only from necessity that I point out—for it is necessary to do so to enable the reader to understand our situation with respect to the Marxist manuscripts that Engels edited—that he was not Marx's intellectual equal and that, while fairly up to the latter's philosophy and sociology, he was particularly deficient in technical economics. Of his own economic publications, *Die Lage der arbeitenden Klasse in England* (1845) will be mentioned again: however biased, it is a creditable piece of factual research, nourished by direct observation. The 'Umrisse zu einer Kritik der Nationalökonomie' (in Ruge's and Marx's *Deutsch-französische Jahrbücher*, 1844) and his *Herrn Eugen Dühring's Umwälzung der Wissenschaft* (1878; English trans. *Anti-Dühring*, 1907) are distinctly weak performances. His philosophical and sociological publications, though not original, keep a higher level. We shall have no occasion to mention either again. But these remarks, let me repeat, should not induce us to think less of the man whose name is fully entitled to the honorific position it holds in the history of German socialism. In par-

Engels who does not properly weigh the implications of their bourgeois cultural background, which is one of the reasons, though not the only one, why Marxism must be considered as a product of the bourgeois mind, a product that grew from eighteenth and early nineteenth-century bourgeois roots. The belief that it ever meant or could mean anything to the masses or in fact to any group, except a limited number of intellectuals, is one of the most pathetic elements in the personal ideology of Marx and Engels.[6] Second, our information enables us to form a pretty clear idea of Marx's opportunities for concentrated work. At times, he indulged in activities and lived under conditions that are bound to get on a man's nerves and to be more destructive of his scientific work than we might infer from the hours actually absorbed. Nevertheless, he had, on the average, an amount of time 'to himself' that compares favorably with the amount that is left, also on the average, to the typical American professor of our own day. And he used it to the full. Again, nobody will ever understand Marx and his work who does not attach appropriate weight to the erudition that went into it—the fruit of incessant labor that, starting from primarily philosophical and sociological interests in his early years, was concentrated increasingly on economics as time went on, until his working hours were all but monopolized by it. Nor was his the kind of mind in which scholarly coal puts out the fire: with every fact, with every argument that impinged upon him *in his reading*, he wrestled with such passionate zest as to be incessantly diverted from his main line of advance. On this I cannot insist too strongly. This fact would be my central theme were I to write a Marxology. Perusal of his *Theorien über den Mehrwert* suffices to convince one of it. And, once proved, it serves to establish in turn another fact and to solve a much discussed riddle: it serves to establish that he was a born analyst, a man who felt impelled to do analytic work, whether he wanted to or not and no matter what his *intentions* were; and it serves to solve the riddle why he failed to finish his work but instead left us heaps of disorderly manuscripts that no labor of love availed to put into an acceptable shape.

Third, our information warrants the statements that he was very much a philosopher dabbling in sociology and politics (as do so many philosophers) until he went to Paris; that there he quickly made headway and found his

---

ticular nothing is further from my mind than a wish to suggest that he was Marx's slave. In the 1840's he may even have helped to educate Marx in economics and in socialism, for at that time he was much further along. There are several biographies. It suffices to mention D. Ryazanov's *Karl Marx und Friedrich Engels* (English trans., 1927, Russian original unknown to me); there is a bibliography of works on both Marx and Engels in Marx-Engels Institute (later the Marx-Engels-Lenin Institute), *Marx-Engels Archiv*, vol. 1, 1926. [The first two volumes of the *Marx-Engels Archiv* were published in German and in a parallel Russian edition; subsequent volumes have been published in Russian only.]

[6] Marx took himself in and helped to foster the same delusion in his followers by building into his structure a sufficient number of phrases—very coarse ones among them—which indeed everyone can understand and which are what Marxism means to the vulgar, perhaps even to people who are not covered by this term.

feet as an economist; and that by the time he and Engels wrote the *Communist Manifesto* (1847; published 1848); that is to say, at the age of 29,[7] he was in possession of all the essentials that make up the Marxist Social Science, the only important lacunae being in the field of technical economics. For the rest, the main line of his intellectual life may be described as a series of efforts to work out that Social Science and to fill those lacunae—*tasks which, I believe, Marx did not expect would involve any insurmountable difficulties, though he did expect that a great deal of further work would be required to straighten out and co-ordinate everything that was to find a place within the vast structure.*

This interpretation is not the usual one. It attributes to Marx an early conception of all that is fundamental in his scheme of thought and, barring points of comparative detail, a large amount of consistency in developing it, springing from a theoretical purpose and plan that never varied in essentials. Even Marxists, who may be expected to sympathize with this view, will find it too simple; but Marx critics will declare it to be downright wrong. Accordingly some defense is necessary. The relevant facts are these. In 1859, Marx published *Zur Kritik der politischen Ökonomie*, which evidently was to be the first installment of a comprehensive exposition and therefore constitutes proof that he must have thought himself equipped to write one. The fact that he abandoned this torso proves that he was not, and that he felt he had made an unsatisfactory beginning. But what of it? This is exactly what must be expected to happen in an enterprise of such magnitude—which, moreover, involves, on the economic side, a large amount of detail, theoretical still more than factual—and cannot be taken as proof that something had gone wrong with fundamentals. He started afresh and, after struggles that are most instructively reflected in some of the manuscript material eventually published in three volumes by Kautsky (*Theorien über den Mehrwert*, 1905-10), brought out a new first installment (*Das Kapital*, first vol., 1867).[8] The fact that no second volume followed during Marx's lifetime and that Engels had to edit the second volume (1885) and to compile a third one (1894), both from unfinished manuscripts, is interpreted by anti-Marxists to mean confession of failure: Marx, so they said, became conscious of the presence in his system of irreconcilable inconsistencies (especially in his value theory), and therefore refused to go on. From the *Theorien über den Mehrwert* it can be shown, however, that Marx, when he published the first volume, was perfectly aware of, and had planned for, what to his critics appeared to be irreconcilable inconsistencies. His correspondence, it is true, establishes the fact that he deferred the completion of the second volume for reasons that do not read too convincingly. But surely this can be explained by the growing resistance of an aging organism that was afraid of new efforts. Thus, the facts mentioned cannot be held to disprove my interpretation. The positive reasons I have for preferring it are his method of work that has been alluded to above, and my theorist's knowledge of what Marx's theoretical difficulties were—from his standpoint, they were not insurmountable. This is, of course, quite compatible with my conviction that Marx's system is seriously at fault. I mean only that he could have presented a comprehensive economic theory without violating logic—he would always have had to do violence to facts.

---

[7] If this be so, it would afford another illustrative instance for Ostwald's theory that thinkers conceive their truly original ideas before they are 30.

[8] This is all I have to say on the question whether and why Marx changed his plan. The question, interesting as it is for Marxology, is quite irrelevant to my interpretation. Any changes of plan are readily understandable in all cases of protracted efforts. See, however, H. Grossmann: 'Die Änderung des ursprünglichen Aufbauplans des Marxschen "Kapitals" und ihre Ursachen,' *Archiv für die Geschichte des Sozialismus und der Arbeiterbewegung*, 1929.

III. Since we have decided to do what Marxists—perhaps rightly—resent, namely, to take the Marxist structure to pieces and to discuss each of these pieces in the places in which they belong, we shall not get an over-all view of it anywhere. The following comments are intended to offer a partial substitute for such a view.

The 'pieces' divide up into two groups, one sociological and the other economic. The sociological pieces include contributions of the first order of importance such as the Economic Interpretation of History, which, as I shall argue, may be considered as Marx's own, quite as much as Darwin's descent of man is Darwin's own. But the rest of Marx's sociology—the sociological framework that, like every economist, he needed for his economic theory—is neither objectively novel nor subjectively original. His preconceptions about the nature of the relations between capital and labor, in particular, he simply took from an ideology that was already dominant in the radical literature of his time.[9] If, however, we wish to trace them further back, we can do so without difficulty. A very likely source is the *Wealth of Nations*. A. Smith's ideas on the relative position of capital and labor were bound to appeal to him, especially as they linked up with a definition of rent and profits—as 'deductions from the produce of labour' (Book I, ch. 8, 'Of the Wages of Labour')—that is strongly suggestive of an exploitation theory. But these ideas were quite common during the enlightenment and their real home was France. French economists, ever since Boisguillebert, had explained property in land by *violence*, and Rousseau and many philosophers had expanded on the subject. There is, however, one writer, Linguet, who, more explicitly than others, drew exactly the picture that Marx made his own: the picture not only of landlords who subject and exploit rural serfs, but also of industrial and commercial employers who do exactly the same thing to laborers who are nominally free, yet actually slaves.[10]

---

[9] It is in this field that Mehring's interpretation of Marxist doctrine (as a verbalization of proletarian ideology) comes nearest to being true. Our quarrel with him is only that he extended this interpretation to the whole of Marx's work.

[10] S. N. H. Linguet (1736-94), a barrister and journalist, was a prolific and bellicose writer, who is difficult to classify. He criticized the physiocrats (*Réponse aux docteurs modernes* . . . 1771) and took part in many controveries of his day without making any mark. But one of his books is of great interest for us, his *Théorie des loix civiles* (1767), neither because of its attack upon Montesquieu nor because of Morellet's biting

This sociological framework offered most of the pegs that Marx needed in order to have something upon which to hang his glowing phrases. And since historians are primarily interested in these, no matter whether they admire them or are shocked by them, it is difficult to gain assent to what is the obvious truth about the nature of the purely economic pieces of the Marxist system. This obvious truth is that, as far as pure theory is concerned, Marx must be considered a 'classic' economist and more specifically a member of the Ricardian group.[11] Ricardo is the only economist whom Marx treated as a master. I suspect that he learned his theory from Ricardo. But much more important is the objective fact that Marx used the Ricardian apparatus: he adopted Ricardo's conceptual layout and his problems presented themselves to him in the forms that Ricardo had given to them. No doubt, he transformed these forms and he arrived in the end at widely different conclusions. But he always did so by way of starting from, and criticizing, Ricardo— *criticism of Ricardo was his method in his purely theoretical work.* Only three outstanding illustrations can be mentioned here: Marx substantially accepted the Ricardian theory of value (see below, ch. 6) and defended it by the Ricardian arguments but, recognizing that Ricardian values cannot be expected to be proportional to prices, tried to work out a different theory of the relation between the two; Marx, following Ricardo's lead, ran up, as Ricardo did, against the problem of surplus value but, recognizing that Ricardo's solution really was no solution at all, developed his exploitation theory from the Ricardian set-up; Marx wholly accepted, down to details, Ricardo's theory of technological unemployment but, finding it inadequate for his purposes, tried to turn into a general 'law' what with Ricardo was no more than a possibility. It is hoped that these points will become clearer as we proceed (chs. 5 and 6). Here they are mentioned by way of anticipation to give definiteness to the meaning of my statements that Ricardo was Marx's master, and that Marx, though he transformed the theoretical material he found, yet worked with tools that he

---

reply, but because it unfolded a quite elaborate historical sociology, the central theme of which was the enslavement of the masses. I do not know that the book had much influence. But, as a symptom at least, it stands at or near the fountainhead of the ideology that Marx and many others, nonsocialists among them, have substituted for capitalist reality, and on which sophomoric enthusiasms feed even today. Linguet supplied not only the picture but also the characteristic spirit with which to look at it. An example will illustrate. Linguet adopts the theory that in the dawn of civilization there were agrarian populations, living in substantially equalitarian conditions, and that a kind of feudal society arose through the subjection of those populations by warlike tribes who established themselves as their lords. There is much to be said for this theory, which is in fact accepted by some modern prehistorians. Now, however, among the results of this subjection that created lords and serfs is everything we include in the term 'culture.' But Linguet has no eye for this. It is the fact of subjection that matters to him and nothing else. And his conclusion is moral indignation and nothing else.

[11] Observe that, so far as theory is concerned, this makes Marx an English economist. And he was one.

found and not with tools that he created. This is only another way of expressing that, however 'secular' a phenomenon Marx may have been in some respects, he was essentially period-bound as a theoretical technician—a fact that later on created many a difficulty for followers who felt unable to admit that Marx could ever grow out of date in any respect.

However, in order to drive home a point that seems important, I have strictly confined myself in the preceding paragraph to Marx's theoretical technique. But there are two features of Marxist theory that transcend technique. And these were not period-bound. The one is his *tableau économique*. In his analysis of the structure of capital, Marx developed Ricardo once more. But there is an element in it that does not hail from Ricardo but may hail from Quesnay: Marx was one of the first to try to work out an explicit model of the capitalist process.[12] The other is still more important. Marx's theory is evolutionary in a sense in which no other economic theory was: it tries to uncover the mechanism that, by its mere working and without the aid of external factors, turns any given state of society into another.[13]

IV. This is all that our space permits us to say about the Marxist system in general and about the manner in which the component parts of it will be taken into account in this book.[14] A reader's guide should follow now. But I feel unable to produce one. Marx was so diffuse and repetitive a writer, and, barring the first volume of *Das Kapital*, his theoretical works reflect so unfinished a state of his argument, that it is impossible to point out what is most significant with any confidence. Instead of attempting an impossible task, I shall refer my readers to a book by Dr. Sweezy (the work of an accomplished theorist and a monument of unswerving loyalty) which presents Marx's economics in the most favorable light and, in addition, is the best introduction to Marxist literature I know.[15] Relying on this reference, I shall confine myself to tendering the following pieces of advice.

---

[12] The next economist to try his hand at this task was Böhm-Bawerk (see below, Part IV, chs. 5 and 6). The affinity between the two is hidden by phraseology and by trappings, but is nevertheless real and close.

[13] Marxologists sometimes speak of Marx's methods' being essentially 'historical.' This phrase carries in this connection two different meanings: it means, first, that different parts of Marxist theory may have been intended by Marx to apply to different states of society; and it means, second, what is meant above by the word 'evolutionary.' Both meanings are capable of defense. But the phrase is infelicitous all the same, because it also carries other meanings—among them the one that is most naturally associated with the word 'historical'—that do not apply to Marxist theory. (On the evolutionary aspect of Marx's theory, see below, ch. 3, sec. 4b.)

[14] The reader need not, perhaps, be told again how incomplete all this is. But there is one point that merits explicit notice. I have emphasized the influence that Smith and Ricardo exerted upon Marx. I have mentioned the influence of Quesnay only as a possibility, because Marx's model might have been developed independently from the Ricardian base. But some other possible influences I have not mentioned at all. Many have been asserted by other historians and, since Marx's knowledge of literature was very nearly exhaustive, the possibility that they are right cannot be excluded. But there is no *cogent* reason for assuming other influences more specific than what is inevitably implied in his having read, analyzed, and criticized very many other people. I have therefore economized space by not mentioning any of the suggestions that have been offered. In fact, as soon as one has grasped the importance of Ricardo's influence, which Marx did nothing to hide, and, in addition, the caliber of Marx's mind, one will automatically cease to be interested in those suggestions, let alone accusations of plagiarism.

There is no point whatever in perusing selected bits of Marx's writings or even in perusing the first volume of *Das Kapital* alone. Any economist who wishes to study Marx at all must resign himself to reading carefully the whole of the three volumes of *Das Kapital* and of the three volumes of *Theorien über den Mehrwert*.[16] Further, there is no point whatever in tackling Marx without preparation. Not only is he a difficult author but, owing to the nature of his scientific apparatus, he cannot be understood without a working knowledge of the economics of his epoch, Ricardo in particular, and of economic theory in general. This is all the more important because the necessity for it does not show on the surface. Again, the reader must be on his guard against being misled by traces of Hegelian terminology. It will be argued below that Marx did not allow his analysis to be influenced by Hegelian philosophy. But he sometimes uses terms in their specifically Hegelian sense, and a reader who takes them in their usual sense misses Marx's meaning. Finally, a reader who wishes for anything other than indoctrination must, of course, learn to distinguish both facts and logically valid reasoning from the ideological mirage. Marx himself helps us in this: sometimes, becoming semiconscious of ideological delusion, he rises, in defense, to the heights of his vituperative rhetoric, which therefore serves to indicate the spots at which there is something wrong.

---

[15] Paul M. Sweezy, *The Theory of Capitalist Development* (2nd ed., 1946). My recommendation does not imply agreement with all of Sweezy's interpretations, especially with his attempt to make a Keynesian of Marx. Attention is drawn to the well-chosen entries in the bibliography, to which I have only one item to add: W. Lexis [J. A. S. here inserted the title of Böhm Bawerk's criticism of Marx, *Zum Abschluss des Marxschen Systems* (1896)—obviously a slip. He probably intended to refer to a review article written by Lexis after the publication of vol. III of *Das Kapital*, namely, 'The Concluding Volume of Marx's "Capital"' in the *Quarterly Journal of Economics*, October 1895]. The importance of Bortkiewicz's contribution has been abundantly emphasized in Sweezy's text.

[16] The *Communist Manifesto* is also indispensable, of course. But for any purpose short of becoming a Marxologist, I think that nothing need be added except the *Class Struggles in France*, articles written in 1848-50, published as a book, with an introduction by Engels in 1895. Only the Marxologist need go into Marx's correspondence.

CHAPTER 2

Socio-Political Backgrounds

1. ECONOMIC DEVELOPMENT 396
2. FREE TRADE AND FOREIGN RELATIONS 397
3. DOMESTIC POLICY AND SOZIALPOLITIK 399
4. GLADSTONIAN FINANCE 402
5. GOLD 405

DURING THE LAST decade or so before the French Revolution, some of the traits became visible of a social and political pattern that, after the revolutionary and Napoleonic Wars and their immediate consequences were over, more or less established itself for the rest of the nineteenth century. It seems desirable to touch upon a few of its essential features, if only to correct some misapprehensions the reader's mind may harbor and to soften the unrealistically definite colors in which the various ideological traditions have painted it.

In doing so we shall have to struggle with a difficulty that is not new to us. We are going to try to visualize an economic and social structure—in process of incessant change, of course—and the cultural superstructure that was either associated with it or, according to Marxist doctrine, generated by it: we call it the civilization or the spirit of the times, or the *Zeitgeist*.[1] But this *Zeitgeist* is never a structural unit. It is always an imperfect synthesis of warring elements and can never be described truthfully in terms of a few consistent 'principles.' The most obvious reason for this is that at any given time both the economic and social structure of a society and its *Zeitgeist* contain elements that hail from historically prior states. But there are other and more fundamental reasons, less easy to explain, which make it impossible to analyze what happens in a social organism in terms of processes that conform to the immanent logic of its state and in terms of processes that are induced by the resistance of survivals or, still more superficially, as 'progress' and 'reaction.' The conceptual arrangement we are going to use bears witness to this difficulty.

On the whole, however, it may be averred that, though the peak of bourgeois *ascendancy* occurred in the subsequent period, it was in the period under survey that the *ascent* of the business class was most nearly unimpeded, most nearly unchallenged. In the great nations, the bourgeoisie did not rule politically, the most important exceptions being the United States and, for the seventeen years of Louis Philippe's regime, France. But in all countries the governments, however unbourgeois in origin and structure, not excluding those that have been voted most 'reactionary' by bourgeois oppositions, backed the economic interests of the business class almost without question and did their best to protect them.[2] Still more important, they did so in a spirit of laissez-faire, that is to say, on the theory that the best way of promoting economic development and general welfare is to remove fetters from the private-enterprise economy and to leave it alone. This is what will be meant in this book by Economic Liberalism. The reader is requested to keep this definition in mind because the term has acquired a different—in fact almost the opposite—meaning since about 1900 and especially since about 1930: as a supreme, if unintended, compliment, the enemies of the system of private enterprise have thought it wise to appropriate its label.

---

[1] The Marxist term *Überbau* is satisfactorily rendered by its literal translation, superstructure. But for the German word *Zeitgeist* there is no perfect equivalent. Hence I am going to use it (as I do other foreign terms that are hard to translate exactly) just as American physicists use *Eigenschwingung* and American philosophers, *Weltanschauung.*

By Political Liberalism, which must be distinguished from economic liberalism as our footnote amply shows, we mean sponsorship of parliamentary government, freedom to vote and extension of the right to vote, freedom of the press, divorce of secular from spiritual government, trial by jury, and so on, including retrenchment and pacific, though not necessarily pacifist, foreign policy. This was the program [3] of the first phase of the French Revolution. A tendency to carry it out eventually asserted itself everywhere. But the rates of speed differed widely as between different countries and so did the combinations of forces and circumstances that were responsible for each step.

The rate at which the business class itself was converted to political liberalism also differed widely, and not only as between different countries, but also as between different subgroups of the bourgeoisie. Not even economic liberalism was welcomed everywhere and by the whole business class; political liberalism came to large sectors of it like an undesired child. The adherents of the Spanish Constitution of 1811, who were the first to call themselves *liberales*, had not the whole bourgeoisie behind them. Neither had the French *libéraux* of the 1820's. It was a wing only, which was but semirecognized and received also nonbusiness support from intellectuals and the masses, that forced the program of political liberalism upon a not-quite-willing majority, though this majority was converted in the end. In England, this shows quite clearly in the way in which first the Whigs and then the Palmerstonians were pushed along by a small group that was known as 'radical.' This group, or at least its intellectual core, the Philosophical Radicals, is of particular interest to us because some of the most important English economists belonged to it or sympathized with it. But unlike their successors of a later day, these radicals were not at all what we should call radical in matters of economic policy. Some of them, J. S. Mill in particular, visualized indeed a different organization of economic activity for a more or less distant future. For the time being, however, they were economic liberals in the sense defined above, or what we should now call conservatives. Their radicalism found plenty to do in the purely political sphere. Moreover, at the beginning of the period, laissez-faire—and in particular free trade—was not as yet established policy. It was something to be fought for, fresh not stale, and something that was felt to be 'progressive.' It attracted the majority of intellectuals instead of disgusting them. Their idea of reform was to clear the economic system of what they regarded as nonessential 'abuses' in order to allow laissez-faire to work itself out fully.[4] They were supporters of the new Poor Law and no friends to Chartism, still less to any of the socialist groups that were in existence then.[5]

---

[2] The Prussian government of the Stein-Hardenberg era, the Austro-Hungarian government from 1849 to 1859, and the Russian government throughout, are the most striking examples of governments that, though surely autocratic enough, adhered, so far as the principles and tendencies of their economic policy is concerned, to what I am about to call economic liberalism. This may read surprisingly. But the reason why it does so is only that these countries were, at the beginning of the period, so far removed from a state of individual freedom in the economic sphere, and that, in their conditions (especially in the conditions of Russia), progress toward this state had to be so slow that the tendency does not show so spectacularly as it does in England. Perusal of any economic history of Europe and, to some extent, the comments that are to follow in the text will, however, convince the reader. In order to understand the economic literature of the period, this fact is of prime importance. Both Prussian and Russian Smithianism was not just a literary fad indulged in by oppositions: its stronghold was in the conservative bureaucracies.

[3] Certain items of it are disputable. For example, men whose right to be called political liberals cannot be denied opposed free public education. Not all liberals sponsored extension of the franchise; some conservatives did.

Thus the correlation between the interests and attitudes of the business class and liberalism was anything but perfect. In addition, as we have already observed, it was by no means only its own left wing that pushed the bourgeoisie along. Conservative governments—and not only the autocratic ones, but also the English conservative governments—had a decisive share in the progress toward economic liberalism. Moreover, groups, strata, parties, and attitudes of noncapitalist origin, though they had to yield occasionally, held their own on the whole. The period's political history bears witness to this. So does its religious history. The period indeed begins and ends with a decade in which indifference or even actively hostile laicism prevailed. But between the Napoleonic Wars and the 1860's, the Catholic Church experienced a marked revival of activity and power that was paralleled in Protestant countries, especially in England (evangelical movement on the one hand, Oxford movement on the other). Nor do the period's currents of thought outside the religious sphere fit into any simple schema. Tory democracy put in an appearance.

---

[4] It is, therefore, understandable that Marx and the Marxists should have professed contempt for bourgeois radicalism—though they transferred their contempt also to the radicalism of a later time—that they should have looked upon it as a sham that was really meant to preserve what it pretended to reconstruct. But understandable though such an opinion is in people who felt themselves to be the competitors of bourgeois radicalism, it is nevertheless quite wrong (1) because radicals and, drawn along by them, simple liberals helped labor to gather in a harvest of considerable value even in the economic field; and (2) because their work in the political field created the conditions under which socialist parties were able to grow to numerical importance.

[5] On the *Chartist Movement*, see the book with this title by M. Hovell (1918).

Naïve radicalism—and the philosophical radicals were nothing if not naïve—certainly did interpret all these things as survivals. Only the subsequent period was to show that, when they thought they fought the past, they were really fighting the future.

A bird's-eye view of the intellectual scenery of the period and of some developments in fields of particular interest to the economist will be presented in the next chapter. The rest of this one will be devoted to a survey of the policies of the period. For brevity's sake, we shall confine ourselves almost entirely to economic policies and to the English paradigm.

1. Economic Development

The liberal intermezzo was everywhere, but most spectacularly in England, associated with an economic development which, so far as we can judge, was unprecedented—all the achievements of the early and middle railroad age. It was easy to attribute that impressive sequence of undeniable successes to the policy of economic liberalism as its main or even only cause. The reader will understand that, however inadequate, this theory was far from being wholly wrong. It cannot reasonably be doubted that, in the historical conditions of that epoch, the removal of fetters from the energies that crowded into business pursuits, together with a policy that guaranteed to the businessman secure enjoyment of success and at the same time made it clear to him that he had no help to expect in case of failure, must in fact have had the energizing influence that was extolled until the argument got stale through repetition. Thus the system kept on justifying itself in the eyes of most contemporaneous observers, even of those who, like J. S. Mill, bore it no love. Such complacent registration of 'progress' seems strange to us who look back upon that age from different standpoints and in a different humor and abhor the atmosphere of the hard-driven homes of rising industrialists almost as much as the squalid dwellings of their workmen. But let us remember that much of all that offends us now was in the nature of childhood diseases—some of which were passing even at the time of Marx's glowing indictments—and that the economic promise, which the system of free enterprise held out *to all*, was not an empty one: the standard of living of the masses remained low, but it rose steadily almost all the time; ever-growing numbers were absorbed at increasing real wages; the 'free breakfast table' of the English free traders was perhaps the least misleading slogan that politicians ever forged. Also, contemporaneous and later critics, both conservative and socialist, have never adequately realized the extent to which the welfare policies of the next period were rendered possible by the developments of the first three quarters of the nineteenth century and by the policies that fostered them. So far as this goes, there is no reason for discounting either the honesty or the competence of the economists of that time, or for voting them victims of ideological delusion.

2. Free Trade and Foreign Relations

The English advocates of free trade claimed perfect generality for their argument. For them, it was absolute and eternal wisdom for all times and places; he who refused to accept it was a fool or a crook or both. But as has been pointed out many times, England's individual historical situation in which a free-trade policy was clearly indicated had probably more to do with her conversion than had the element of general truth in the free-trade argument. The hope that a spectacular example would convert other nations also may have played some role. The decisive factors and arguments, however, were quite independent of any such hope. The superiority of England's industry in 1840 was unchallengeable for the calculable future. And this superiority had everything to gain from cheaper raw materials and foodstuffs. These were no delusions: so satisfied was the nation with what it took to be the results of this policy that criticism was almost silenced until the depression of the eighties. Even that hope did not prove illusory for several decades. Though England remained the only great nation to embrace free trade wholeheartedly, all the other nations displayed tendencies toward free trade for longer or shorter periods and to a greater or lesser degree. Thus Prussia and then the German Empire, from the Prussian Tariff of 1818 to the Caprivi treaties of 1891-4, moved on a line that never departed very far from free-trade principles.[1] The Anglo-French treaty of 1860 (Cobden-Chevalier Treaty) marked an important if short-lived interruption in the generally protectionist policy of France. It should be observed, however, that on the Continent free-trade or quasi-free-trade policy was never supported by public opinion as strongly as was the case in England: it was imposed by bureaucracies—as in Germany—or by rulers—such as Napoleon III—who were doctrinaire liberals in these matters. Those economists who, like the majority of the French, were free traders elicited little response from the public. In the United States, too, free trade was never popular except with economists and not with all of them. Different national conditions of course amply account for this, and they also enable us to put a more favorable construction on the views of protectionist economists in these countries than ardent free traders were wont to put upon them. The dramatic story of England's conversion to free trade need not be retold here. But there are two aspects of it that we cannot afford to neglect.

First, from a parliamentary point of view the adoption of the free-trade policy stands wholly to the credit of the conservative party. The first effective steps in the direction of free trade were taken before the outbreak of the French Revolution by Lord Shelburne and the younger Pitt. Advance toward it was resumed in the 1820's by Huskisson. And free trade was (substantially) carried, the most difficult point—removal of the import duties on grains—included, by the conservative government of Sir Robert Peel. Though his cabinet and party foundered on the rocks, it still remains true that a government largely composed of landowners carried a policy that was obviously contrary to their own economic class interests as well as to the economic interests of the class with which they were most closely allied, the farmers. Interpret it as you please, but do not forget to ponder over this most interesting phenomenon of political sociology. The manufacturers and merchants who provided political steam are another matter. The Merchants' Petition of 1820 must be mentioned because it was drawn up by one of the leading scientific economists of the age, Thomas Tooke. And this is our only opportunity, in a history of *analysis* to mention the two heroes of the Anti-Corn-Law League, Richard Cobden and John Bright.[2]

---

[1] The fact is somewhat obscured by the moves and countermoves that preceded the conclusion of the Customs Union (*Zollverein*) of 1834 and by concessions made from time to time to individual protectionist interests. On the whole, however, the policy of the Customs Union and, for the rest of the century, of the Empire is adequately described by the sentence above. Bismarck's mild protectionism had mainly fiscal reasons.

But, second, free-trade policy means much more than a particular way of dealing with questions of foreign trade. In fact, it could be argued that this is the least important aspect of it and that a man might be a free trader, even if he thinks little of the purely economic case for free trade per se. It is easy to see—to some extent we shall see presently—that free-trade policy is related to other economic policies in such a manner that, for political as well as economic reasons, these other policies are difficult to pursue without free-trade policy, and vice versa. In other words, free trade is but an element of a comprehensive system of economic policy and should never be discussed in isolation. Nor is this all. The really important point to make is that this system of economic policy conditions, and is conditioned by, something that is more comprehensive still, namely, a general political and moral attitude or vision that asserts itself in all departments of national and international life and *may* indeed be linked up with utilitarianism.[3] This attitude, which has come to be called *Manchesterism* by its enemies, was in fact Cobden's and Bright's. Among its many manifestations, colonial and foreign policies are particularly important for us. Colonies used to be acquired for the sole purpose of being ruled and exploited in the interest of the mother country and of keeping other nations from doing the same thing. From the Manchester school standpoint there is not even an economic argument in favor of doing this. Still less is there a political one. Colonies exist for themselves just as do any other countries; they should be self-governing; and they should neither accord to, nor be accorded by, the mother country any particular commercial advantages. Nor did all this remain in the realm of either philosophy or agitation. Some practical progress was made toward the goal. England's Canadian policy, as outlined in the Durham Report, was for the time being the most important step.[4] There were many backslidings, of course.

---

[2] It may seem incongruous, in spite of all I might say, that this book accords but a perfunctory notice to those great names. But there is nothing I can do about it except refer the reader to the two masterly lives that he will peruse with pleasure and profit: the *Life of Richard Cobden* by Lord Morley and the *Life of John Bright* by G. M. Trevelyan.

[3] In England, this affiliation was obvious. But it is not necessary—there are other systems of thought that yield the same attitudes.

The foreign policy of the period, both at the time of the Holy Alliance and later, cannot be analyzed briefly. So far as England is concerned, we may, however, point to a few facts which, though hardly representative of prevailing practice, do indicate the existence of a tendency that was in accord with the wider implications of free trade. The most important of these facts was the actual practice of the second Peel administration, the one that repealed the Corn Laws: its sober and responsible management of foreign affairs, its refusal to see English interests in whatever happened anywhere on the globe, was an important sign of the times. Another was the adoption of the principle (Canning) to side with nations 'rightly struggling to be free' or even, with some reservation in the German case, with nations that strove for national union: nationalism did not have the connotation it later acquired and was an ally, not an enemy, of bourgeois liberalism or else of something to the left of it (Mazzini). Furthermore, though the period witnessed a number of wars, others were prevented by the new attitude: English relations with the United States during the Civil War afford an example. Most important of all, attempts at sowing the seeds of war by arousing a spirit of either aggression or suspicion, which of course continued throughout, were also under criticism throughout: as an example I mention Cobden's highly characteristic struggle for a better understanding of France and his not less characteristic struggle with Urquhart.[5] In parliament, Gladstone became—and remained—the most powerful spokesman of the new attitude which he invested with all the glories of his rhetoric.[6]

3. Domestic Policy and Sozialpolitik [1]

We must remember that conditions differed sufficiently in different countries to produce different policies and also different attitudes on the part of economists even where the guiding principles were the same. Thus the abolition of serfdom in Russia and the agrarian reforms in Germany and Austria—the so-called Liberation of the Peasants—were certainly conceived and carried out in the spirit of economic liberalism: the idea of making the peasant the free proprietor of a free holding and of leaving him to his own devices was even surprisingly—and indeed absurdly—radical. But in France this had been done in the Revolution; the land system of England presented for the moment no pressing problems at all; and the agrarian problems of Ireland were of an entirely different nature. Similarly, the regulations that fettered or sheltered the craft guilds and also other sectors of industry had withered away in England before this period; in France it was again the Revolution that had destroyed them; elsewhere they were removed at different times and in some places much more completely than in others: in Prussia, for example, by the Stein-Hardenberg reforms after the battle of Jena. These differences were, however, not a matter of different economic principles, although writers may sometimes have rationalized them in this way. They were merely a matter of different social conditions, of differences in the economic structures that existed in different countries at the beginning of the period. Again, England completely reconstructed her law of joint stock companies. To some extent this was done everywhere, and everywhere the tendency asserted itself to 'liberalize' company laws and to reduce public control (until after the crash of 1873 when some of the steps taken were retraced). But the results differed widely.

---

[4] See Charles P. Lucas, ed., *Lord Durham's Report on the Affairs of British North America* (1912). Lord Durham (1792-1840) submitted his report in 1839.

[5] David Urquhart, a former member of the diplomatic service, founded in 1835 a periodical, the *Portfolio*, and, later on, foreign-affairs committees that made vigorous propaganda for an activist foreign policy. Cobden subjected to destructive criticism the possible advantages from such a policy, made fun of arrogant and ignorant diplomatists and political busybodies, and on the whole counteracted Urquhart effectively.

[6] Perhaps the best, certainly the most pleasant, way for the reader to satisfy himself as regards this point is a perusal of Lord Morley's great Gladstone biography (*Life of William Ewart Gladstone*, 3 vols., 1903). This is also perhaps the best reference to make for the rest of this chapter.

[1] As I said before, I prefer a word that everyone understands, even though it is a foreign one, to one that would need explanation. Hence we shall use the word *Sozialpolitik* throughout.

Differences of principle as well as of existing conditions account for the widely different policies we find in such matters as religion, the press, criminal and civil justice, education, and so on, within the same country at different times as well as between different countries. In England, for example, the old civil liberties having been restored after the Napoleonic Wars, it was Catholic emancipation, parliamentary reform—at first a liberal patent, later infringed on by the Disraeli conservatives [2]—and Ireland which supplied the daily bread of current politics in the noneconomic field. But we are mainly interested in the English [3] *Sozialpolitik* of that period.

---

[2] In England, the running fight for the ultimate enfranchisement of the masses was carried on entirely between upper-class groups: the masses themselves had nothing to do but to stand by and cheer or boo. This interesting phenomenon illustrates well a characteristic difficulty of political interpretation. Tactics had much to do with the attitudes taken by Whigs and Tories: Catholic emancipation 'drove the Whigs back upon parliamentary reform' and the Whig parliamentary reform in turn drove the Tories back upon further parliamentary reform. But tactics are not all of it. There is something in Disraeli's contention that conservatism of his type (Tory democracy) represents the true interests and feelings of the masses and hence should look to the masses for support.

[3] As the reader might expect, the paternalistic tendencies of the preceding period survived better in some continental countries. But there is something else. In France, before the accession to power of Napoleon III, socialist movements had had little practical effect except that of eliciting violent hostility. But there were nevertheless some writers who visualized with perfect clarity the governmental *Sozialpolitik* of later times. By far the most eminent of these was Charles Dupont-White (1807-78); see his *Essai sur les relations du travail avec le capital* (1846) and his *L'individu et l'état* (1857). Napoleon III and some of his advisers entertained fairly advanced ideas on the subject of social reforms that were to be imposed by authority (*socialisme autoritaire, so-*

English labor legislation developed along three lines. First, there was the factory legislation—protection being, however, substantially confined to women and children.[4] Second, the various acts prohibiting combinations of workmen were repealed in 1824, though complete legalization of trade unions was deferred until 1871 and 1875. Third, a Poor Law Amendment Act was passed in 1834, which is important for us, among other reasons, because it was based on a report written by Edwin Chadwick in collaboration with one of the leading economists of the age, Senior. Two aspects of this act must be carefully distinguished. On the one hand, it greatly improved the administrative machinery of poor relief and stopped a number of practices that would be considered abuses even now. This was almost universally recognized, though some critics found fault with the act's administrative scheme. In any case, this aspect does not concern us here. On the other hand, the act adopted certain economic principles that do concern us. They were by no means new. In fact, they were as old as the poor-law controversy: the act simply adopted the views of one party to the controversy. That is to say, it confined poor relief to maintenance in the workhouse and prohibited outdoor relief on principle,[5] the idea being that the able-bodied unemployed, who were in distress, should not indeed be left to starve but should be maintained in semipunitive conditions.

Interpretation of these policies is an extremely delicate matter. We cannot do much more than visualize the various groups of problems that arise. First of all, these policies must not be considered in isolation. They were part of a system that offered other things to the working class. If we assign its proper weight to the effects on the real wage bill of the free-trade policy and to all that the 'free-breakfast table' implies, we shall conceive a wholly different idea of the period's performance in *Sozialpolitik*. Second, it is by no means clear how these policies fit in with economic liberalism. As regards the factory legislation, for example, it is as easy to argue that it was part of the logic of economic liberalism as it is to argue that it spelled deviation from this logic. I suggest that, as far as protection for women and children is concerned, we adopt the former opinion. Third, it must not be forgotten that though this type of factory legislation enjoyed some liberal or radical support—Cobden came out strongly on behalf of the children—the bulk of the political forces that carried it was supplied by conservatives (Lord Ashley, seventh Earl of Shaftesbury), who approached this whole range of problems in a quite different spirit. This fact is significant, no matter how we answer the question of compatibility of social legislation with the logic of economic liberalism.

Contemporaneous and later critics, German exponents of *Sozialpolitik* in particular, have accused the English 'classic' economists of cold indifference

---

cialisme d'état), and some practical measures were actually taken. Dupont-White may be considered the literary exponent of this type of *étatisme*.

[4] A reference must be substituted for information that cannot be presented here: Hutchins and Harrison, *A History of Factory Legislation* (new ed., 1907).

[5] It soon proved impossible to enforce this principle where there was serious resistance.

to the fate of labor. The first thing to be said about this is that the indictment reveals a lack of historical sense that is particularly strange in critics associated with the German historical school: the man who disapproved of a ten-hour bill in 1847 might easily be a New Dealer in modern America without our having any right to impugn his consistency. But we can go further. Most 'classic' economists supported the factory legislation, McCulloch especially. The repeal of the Combination Acts was vigorously pushed by a member of the Benthamite circle (Place [6]). And the Poor Law Amendment Act, which was almost unanimously supported by economists, has other aspects besides what seems to us harsh treatment of people in distress. At the same time, we must not go too far. The support that 'classic' economists gave to this act acquires additional significance from the fact that the theory underlying it tallied well with their general scheme of economic and political thought, their scheme of Natural Liberty. It also tallied well with their views on population and wages. It tallied still better with their almost ludicrous confidence in the ability of individuals to act with energy and rationality, to look after themselves responsibly, to find work, and to save for old age and rainy days. This, of course, is Benthamite sociology, hence bad sociology. On this point, the critics were right, however wrong they were in imputing to the 'classics' a defective social conscience.[7]

4. Gladstonian Finance

In the field of fiscal policy, we are more prone than we usually are to give the jockey credit that is really due the horse. P. J. Cambon was an able financier, yet all the reader is likely to know about the finances of the French Revolution is the breakdown of its paper money.[1] F. N. Mollien was a master of the art, but under the conditions of the Napoleonic regime he had no chance to produce 'great' fiscal policy [2]—and there are several others who deserve our respect though they have left a checkered record. Yet there was one man who not only united high ability with unparalleled opportunity but also knew how to turn budgets into political triumphs and who stands in history as the greatest English financier of economic liberalism, Gladstone.[3] We cannot do better than consider him alone.

---

[6] On this interesting man, see Graham Wallas' *Life of Francis Place* (1898), one of those books that bring past milieus back to life.

[7] Nor is it quite true that all the 'classics' were liberals in the party sense; Malthus was not a liberal. But most of the others were; and there is some truth in speaking of an 'alliance' of 'classic' economists with the liberal party. Therefore, by virtue of psychological, though not of logical association, the later decline of political liberalism *contributed* to the decline of the prestige of 'classic' economics. Observe, however, that there is a long way between recognizing this and identifying 'systems' and their fortunes with the political humors of the hour.

[1] This gives me the opportunity to call the reader's attention to the important bibliography on the finances of France in the eighteenth century by René Stourm (*Bibliographie historique des finances de la France au dix-huitième siècle*, 1895).

[2] François N. Mollien's *Mémoires d'un ministre du trésor public*, 1780-1815 (1845), however, rise in places to the level of scientific analysis.

The greatest feature of Gladstonian finance—the feature that it shares with, and which may be said to define, all 'great finance'—was that it expressed with ideal adequacy both the whole civilization and the needs of the time, *ex visu* of the conditions of the country to which it was to apply; or, to put it slightly differently, that it translated a social, political, and economic vision, which was comprehensive as well as historically correct, into the clauses of a set of co-ordinated fiscal measures. This applies both to the measures themselves and to the intuition that bore them, but not to the talk of the day, Gladstone's own included, which was highly doctrinaire. We are not interested in the details of these measures but only in the principles involved. Let us try to state them.

Gladstonian finance was the finance of the system of 'natural liberty,' laissez-faire, and free trade. From the social and economic vision that this implies—and which we must now understand historically, irrespective of all general arguments pro and con—the most important thing was to remove fiscal obstructions to private activity. And for this, in turn, it was necessary to keep public expenditure low. Retrenchment was the victorious slogan of the day and was even more popular with radicals—such as Joseph Hume, the 'sleepless watchdog of finance'—than it was with either Whigs or Tories. Retrenchment means two things. First, it means reduction of the functions of the state to a minimum; this was referred to by later, especially German, critics as the policy of the 'night-watchman state.' For instance, within that social vision there is hardly any place for public expenditure on art or science: the way to further art and science—and powerfully furthered they were—is to allow people to earn so that they have the money to buy pictures or to enjoy leisure for research.[4] Second, retrenchment means rationalization of the remaining functions of the state, which among other things implies as small a military establishment as possible. The resulting economic development would in addition, so it was believed, make social expenditures largely superfluous. Observe once more that all this, wholly wrong if cast into terms of timeless general principles, did contain a large element of truth for England in 1853.

---

[3] The most spectacular of those triumphs was won by the budget of 1853. The reader will do well to familiarize himself with its main features. He finds these described, in the whole political setting and in all their rhetorical glory, in Lord Morley's Gladstone biography already referred to.

[4] In a well-known passage, Ruskin (see below, ch. 3) upbraided English governments for refusing, unlike continental governments, to spend money for the encouragement of the arts. This is an interesting instance of a type of social criticism that always fails to see a social system as a whole. It was Ruskin's *right* to prefer other methods of encouraging art. But it was his *duty*, as an analyst of social phenomena, to realize that the English method of doing so, even if inadequate, was a method and not just nothing. Independently of this, he should have further recognized that inadequacy of the English method was not obvious from results. This also holds for the sciences and, among others, for economics. If we view results in historical perspective and in particular attach due weight to *originality* of research, we shall not find it easy to aver with confidence that this social system was less productive of artistic and scientific achievement than is the modern system that uses different and more direct methods. I emphasize this because the principle involved is very important in the field of technical economics: for instance, present-day Keynesians are within their rights, logically,

Equally important was it, from the same vision of economic opportunities and mechanisms, to raise the revenue that would still have to be raised in such a way as to deflect economic behavior as little as possible from what it would have been in the absence of all taxation ('taxation for revenue only'). And since the profit motive and the propensity to save were considered of paramount importance for the economic progress of *all* classes, this meant in particular that taxation should as little as possible interfere with the net earnings of business. Therefore, so far as direct taxation is concerned, no progression. In principle, if not in practice, Gladstone went even further than this in 1853. The Napoleonic Wars had brought the income tax (in the English sense). It had been abolished promptly when the emergency was over (1816), but had been reintroduced by Peel (1842) in order to make good the deficiency expected from his reductions of import duties.[5] But Gladstone proposed in 1853 to abolish it again in seven years.[6] As regards indirect taxes, the principle of least interference was interpreted by Gladstone to mean that taxation should be concentrated on a few important articles, leaving the rest free. This opinion prevailed throughout against that of Sir George Cornewall Lewis, the Chancellor of the Exchequer during the Crimean War, who preferred a system of numerous duties that would bear lightly on every point touched.[7]

Last, but not least, we have the principle of the balanced budget or rather, since debt was to be reduced, the principle that Robert Lowe, one of the

---

when they aver that the capitalist mechanism that tends to equilibrate *ex ante* saving and investment is weak and apt to stall; but if they aver that it does not exist, they are simply committing a definite and provable mistake.

[5] The same policy was adopted by the Wilson administration in 1913.

[6] In fact, he kept to this idea throughout. In his electoral manifesto of 1874 he pronounced again in favor of total repeal. The question how far this is consonant with the creed of economic liberalism is difficult. An income tax so high as to change distribution of income substantially certainly is not. This would clearly conflict with the principle of 'taxation for revenue.' But an income tax of a few per cent, even if progressive, seems to me to fit the Gladstonian vision better than does the course he actually took.

[7] Economically—though perhaps not administratively—Lewis was right, I think. Gladstonian orthodoxy overlooked another point also. It was strongly against taxing 'necessities.' In fact, this principle, together with the free-trade policy, was the greatest *direct* contribution of Gladstonian finance to social welfare (though we must, in order to appraise its total contribution, keep in mind that this direct contribution was not its only one: in addition it did something toward helping into existence the wealth that later proved so easy to tax in the interest of the masses). But this exclusive emphasis on the distinction between 'necessaries' and 'luxuries' fails to do full justice to the implications of the distinction between commodities that are elastic and commodities that are inelastic in demand.

Chancellors of the Exchequer of the Gladstonian era, embodied in his definition of a minister of finance: 'an animal that ought to have a surplus.' Again, there is no point whatever in criticizing either the policy of balancing the budget or the policy of debt redemption from modern standpoints. Even if we grant all that modern advocates of deficit financing claim, we should admit that in a world bursting with 'investment opportunities' neither policy can be set down as unalloyed nonsense.

5. GOLD

The little that need be said for our purposes on the currency and banking policies of that period will be more conveniently reserved for the last chapter of this Part. In consequence, there is only one point to make here. After the monetary disturbances—the inflation—incident to the Napoleonic Wars, all countries struggled back to what was considered normalcy. This took many decades in such countries as Austria, but was achieved promptly and with comparative ease in England and France. On the Continent, normalcy meant silver or a bimetallic standard, but England, after having legalized the de facto gold standard established in the eighteenth century, resumed gold redemption of Bank of England notes within a few years of Waterloo, much as she returned to gold at prewar parity (though in a somewhat different form) after the First World War of our time. Moreover, it was a perfectly 'free' or 'automatic' gold standard that allowed for no kind of management other than is implied in the regulatory power of any central bank that is 'a lender of last resort.' Our question is: why? The measure drew fire from many quarters, even from some economists. Powerful agrarian interests attributed to it—never mind now whether rightly or wrongly—the depression that plagued them. There was enough unemployment to induce the government (Castlereagh, 1821) to propose public works—an almost Rooseveltian program—as a remedy. Merchants do not relish losses, nor bankers frozen assets—and there were plenty of both. Also, we shall see that many competent people advocated a managed paper currency. Nevertheless, the gold-standard policy was never in real danger politically, and if it was not, until much later, adopted by all industrialized countries, this was not a matter of their choice: in spite of all counterarguments, the 'automatic' gold standard remained almost everywhere the ideal to strive for and pray for, in season and out of season. Again: why?

At present we are taught to look upon such a policy as wholly erroneous—as a sort of fetishism that is impervious to rational argument. We are also taught to discount all rational and all purely economic arguments that may actually be adduced in favor of it. But quite irrespective of these, there is one point about the gold standard that would redeem it from the charge of foolishness, even in the absence of any purely economic advantage—a point from which also many other attitudes of that time present themselves in a different light. An 'automatic' gold currency[1] is part and parcel of a laissez-faire and free-trade economy. It links every nation's money rates and price levels with the money rates and price levels of all the other nations that are 'on gold.' It is extremely sensitive to government expenditure and even to attitudes or policies that do not involve expenditure directly, for example, to foreign policy, to certain policies of taxation, and, in general, to precisely all those policies that violate the principles of economic liberalism. *This* is the reason why gold is so unpopular now and also why it was so popular in a bourgeois era. It imposes restrictions upon governments or bureaucracies that are much more powerful than is parliamentary criticism. It is both the badge and the guarantee of bourgeois freedom—of freedom not simply of the bourgeois *interest*, but of freedom in the bourgeois *sense*. From this standpoint a man may quite rationally fight for it, even if fully convinced of the validity of all that has ever been urged against it on economic grounds. From the standpoint of *étatisme* and planning, a man may not less rationally condemn it, even if fully convinced of the validity of all that has ever been urged for it on economic grounds.

---

[1] Of course, it is never quite automatic and this phrase is misleading. I use it here for the sake of brevity and do not mean by it more than that all other means of pay-

---

ment should be redeemable in gold and that everyone should have the right to import and export, monetize or demonetize, gold at will.

CHAPTER 3

The Intellectual Scenery

1. The Zeitgeist of the Period and Its Philosophy 407

1. The Zeitgeist of the Period and Its Philosophy

The truth of our proposition that the *Zeitgeist* of a period can never be defined in terms of a single system of mutually consistent ideas or beliefs is brought home to us when we turn to the philosophical currents of that time in order to discover the philosophical affiliations, if any, of the social sciences.

(a) *Utilitarianism.* The most obvious of these affiliations is with English utilitarianism.[1] This was indeed a product of the eighteenth century. But it ran the best part of its career in the first half of the nineteenth. No philosophy at all in the technical sense,[2] unsurpassably shallow as a 'philosophy of life,' it fitted to perfection the streak of materialistic (antimetaphysical) rationalism that may be associated with liberalism and the business mind. Actually, however, the majority of the English business class did not accept it but, whether Anglican or nonconformist, kept to the religious philosophy of either Church or Chapel. The utilitarian leaders evidently knew why they were so careful not to affront religion openly.[3] And all leading politicians knew why they left utilitarianism severely alone. Its appointed apostles, the philosophical radicals,[4] were at first a very small circle that gathered around Bentham and James Mill. J. S. Mill cannot be called a utilitarian without qualification. In some respects he outgrew the creed; in others he refined it. But he never renounced it explicitly, and it was through his influence upon the rising generations in the 1850's and 1860's that a more sophisticated utilitarianism established itself in the intellectual centers, especially in Cambridge. But it did not not become dominant. This seems to be clear from an analysis of the position of the men who were then or later became leaders of Cambridge life and thought, particularly of Sidgwick.[5]

---

[1] See Sir Leslie Stephen, *The English Utilitarians* (1900).

[2] Evidently, the 'calculus of pleasure and pain' and the principle of 'greatest happiness for the greatest number' do not, in themselves, assert anything about specifically philosophical or epistemological problems, though they are capable of producing an ethical doctrine. The reason why this speculative deficiency of utilitarianism was not

It will be maintained later that there is no point in calling Ricardo a utilitarian, though he was personally connected with the group and may have professed sympathy with its creed. Bentham, James Mill, and (with qualification) J. S. Mill were the only prominent economists who were also prominent and militant utilitarians, as Beccaria and Verri had been in the eighteenth century. It was natural for Bentham and the Mills to see themselves in the role of philosophical patrons of economics and to assume responsibility for an alliance between economics and utilitarianism that was acquiesced in by many later economists, such as Jevons and Edgeworth; but it was neither necessary nor useful. This alliance is the only reason why utilitarianism looms so large in the economist's picture of nineteenth-century thought, much larger than is

---

more keenly felt was that utilitarians found what they wanted ready at hand in the empiricist tradition of the Locke-Hume type.

[3] J. S. Mill's *Three Essays on Religion* appeared posthumously in 1874. The views on religion that are contained in his elaborate *Examination of Sir William Hamilton's Philosophy* (1865) probably did not filter through to the general reading public.

[4] See e.g. C. B. R. Kent, *The English Radicals* (1899); E. Halévy, *La Formation du radicalisme philosophique* (1901-4; English trans. 1928).

[5] Henry Sidgwick (1838-1900) really has claim to more attention than we can bestow upon him. His work in economics will be noticed in passing where it belongs chronologically, but there is little in his eminently reasonable rendering of 'classic' doctrine to call for comment in a sketch like this. Nor, I am afraid, would a historian of ethics or politics—the other two fields in which he produced major work—be able to say more. But he was one of the greatest English university men all the same: milieu-creating, milieu-leading, soul-shaping to an extraordinary degree. Perhaps lack of originality is one of the conditions for this particular type of academic achievement. Of all the Cambridge leaders, he was—with his antimetaphysical mind that was so lucid and so wingless—the one most favorably disposed to accept utilitarian starting points. Nevertheless, his ethics cannot be called straight utilitarianism, and this is the test, for it is here that a utilitarian creed, *qua* philosophy, would have to assert its sway.

justified by its importance either as a philosophy or as a factor of the *Zeitgeist*. We must digress for a moment in order to consider the effects of that alliance upon economics. The reader will recall that, for earlier epochs, we have dealt with this question already.

Since economists, especially nontheorists, are and always have been apt to entertain exaggerated notions about the importance of philosophical backgrounds upon the positive work of economic analysis, we shall understand that this alliance made English economic theory unpopular in many quarters. Especially with some German writers the utilitarian garb was quite sufficient for wholesale condemnation of the theory that appeared in this guise. More interesting than this attitude, which rested upon nothing but an obvious misunderstanding, is, however, the question of the real influence of utilitarian philosophy upon the contents of 'classic' economics. We must distinguish influence upon policy recommendations, economic sociology, and economic analysis proper. As regards the 'classic' recommendations, there are no doubt many that are wholly neutral with respect to any philosophy of life: one need not be a utilitarian in order to recommend peasant proprietorship for Ireland, or in order either to recommend or condemn return to the gold standard after the Napoleonic Wars. But there are others—unconditional free trade, for example—that did imply views of general policy and attitudes to life that do seem, to say the least, to link up with utilitarianism better than with any other philosophy of life. As regards economic sociology, utilitarianism can only be described as a complete failure since its rationalistic conception of individual behavior and of social institutions was obviously and radically wrong. But as regards that part of economic analysis which works with rational schemata, utilitarian philosophy, though superfluous, does no harm. And this fact, as critics would have recognized if they had been competent economists, salvages the bulk of the work in economic analysis done by the utilitarians.[6]

Professional philosophy in England, mainly the philosophy of the Scottish common-sense school, was but moderately affected by utilitarianism and was, on the whole, hostile to the utilitarian way of disposing of specifically philosophical problems. But there was during that period no leader of English philosophical thought strong enough to counteract the able and vigorous propaganda of the philosophical radicals. Leaders of thought that did counteract it to some extent were produced by the romantic (see below, sec. 2) and several religious movements. A leader of still another type might be mentioned here, Carlyle.[7] For economists he is one of the most important and most characteristic figures in the cultural panorama of that epoch—standing in heroic pose, hurling scorn at the materialistic littleness of his age, cracking a whip with which to flay, among other things, our Dismal Science. This is how he saw himself and how his time saw and loved to see him. Completely incapable of understanding the meaning of a theorem, overlooking the fact that *all* science is 'dismal' to the artist, he thought he had got hold of the right boy to whip. A large part of the public applauded, and so did some economists who understood no more than he did what a 'science' is and does. But the digression above on utilitarian economics shows that he was not wholly in error. The utilitarian economists did advocate policies indicative of a philosophy of life that fully deserved all the stripes that Carlyle administered. And the reader should for a moment stop to ponder over the difficulty that has so much to do with the futility of so many of our controversies, namely, the difficulty that both the professional and the public mind experience in disentangling the analytic aspect of such cases from the cultural philosophy that goes with it, and in realizing that adverse criticism of the former is perfectly compatible

---

[6] Of course, this should not be understood to mean that this work was not open to objection on other grounds.

[7] Thomas Carlyle's (1795-1881) fame rests on the solid basis of his historical works that are too well known to be mentioned here. But one should not call him a historian without adding that, besides being much else, he was a historian *sui generis*. He

---

painted portraits in the style and spirit of the artist. Though these portraits rest on sound and often minute research, they render artistic not scientific interpretations. The modern reader will be amazed to miss economic and social facts almost completely. And he will turn away with something like disgust from the overemphasis on the personal element that he finds everywhere. Yet this is not quite what he should do. By itself Carlyle's 'hero worship,' which seems to make history a tissue of individual biographies, is not indeed acceptable sociology. But in times when the personal element and its explanatory value are in danger of being drowned in statistics and when the 'common man' holds the stage, Carlyle's hero worship, by stressing the forgotten factor, personality, comes in as a useful antidote. Directly relevant to the history of economics are his *Chartism* (1840), *Past and Present* (1843), and *Latter-Day Pamphlets* (1850).

Carlyle's emphasis upon the element of personality (the contrast with Bentham, who was individualist without being a 'personalist,' should suffice to show that the two are entirely distinct) calls up the name of R. W. Emerson (1803-82), who was, to use his own phrase, another Representative Man. With him, that emphasis did not amount to hero worship, and to this extent his contribution to a sociological schema of the historical process is sounder though less original than is Carlyle's. Emerson did not cross swords with 'classic' economics. But from another angle he is still more important for us: his thought, the focus of many currents and the source of others, *was the adequate expression of the civilization of that age as it mirrored itself in the particular conditions of the New England environment*. This I conceive to be his claim to eminence in the history of thought. I am sorry this sounds involved. However, since it is impossible to describe that (New England) intellectual and moral environment in the available space, we must leave it with this sentence. Nor can we afford to stay to look at the Concord and Cambridge (or Boston) circles with which, directly and indirectly, Emerson and his associates were connected. This is all the more regrettable because they are the sources of an important component of a specifically American radicalism that influenced the attitudes of American economists long after those circles themselves had disappeared, and accounts for much that a European finds hard to understand. A study of Thoreau's writings might prove particularly enlightening. (On the 'social science movement,' see below, sec. 6a.)

with admiration for the latter and vice versa. Something, however, may be said for Carlyle even from the analytic point of view: he had the vision, though he had not the means to make it analytically articulate, of an economic sociology that was much more realistic than was the utilitarian. What a nation is and really wants and what are the real determinants of its fate, he saw much more clearly than did Bentham; the analysis that might be distilled from his pages would take account of a number of important facts that Bentham ignored or, at all events, brushed aside, because from the standpoint of his creed they were simply irrelevant aberrations. J. S. Mill sensed this to some extent. He grew to realize that the scheme of utilitarian rationality is quite inadequate beyond a limited range of problems. But he was not the man to make anything of it, and so the vision of one man and the analytic power of another never met to work together. Carlyle influenced another but (for us) much less important prophet, Ruskin, who, though his writings on economic subjects belong to the subsequent period, shall therefore be mentioned here.

Almost throughout the period under discussion, John Ruskin (1819-1900; any work of reference will give the reader all that is needed to appreciate the points to be made in this paragraph) was one of those creative interpreters of art—painting, architecture, sculpture, and also poetry—whose interpretations are themselves works of art, works that have a life of their own and elicit admiration even in those who (like myself) do not believe in them *as interpretations*. For us, it is particularly important to note his contributions to a general sociology of art, his attempts to analyze the social conditions that produce, or are favorable to the production of, great works of art. From the end of the 1860's on, he turned, however, to the mission that was to make him so popular with the crowd as well as with economists of radical propensities—wrathful and dilettantic criticism of the sins of capitalism: the reader will quickly acquire an adequate notion of this criticism by dipping into *Unto this Last* (1862), *Munera Pulveris* (1872), and *Fors Clavigera* (1871-84), all in *The Works of Ruskin*. I have only one point to make. There is a definite reason for objecting to Ruskin's way of handling economic problems (I am not speaking, of course, of his generous and not unsuccessful practical work in the interest of the welfare and civilization of the masses): he failed to do in this field what he did as a matter of course in the field of art. We know that he prepared himself most sedulously for his career as an interpreter of art; that he mastered techniques and studied historical detail according to the canons of scholarship. It is 'genius' that speaks from his interpretations, but genius tutored and made effective by learning. In the field of economics he did nothing of the sort; all he did was to add generous indignation to half-understood observations and undigested pieces of reading. It is this and *not* his evaluations (with which many of us will sympathize) that puts him out of court, except for such writers as J. A. Hobson. The judgment I pass on him—and he stands for so many—is exactly the same that he himself would have passed on any writer who undertook, for example, to criticize Turner's paintings without having previously acquired, by morally neutral study, an adequate mastery of the relevant facts and techniques.

(b) *German Philosophy*. The reader presumably knows that the first part of the period under discussion witnessed the peak achievements of German speculative philosophy, and the names of Kant, Schelling, Fichte, Hegel, and Schopenhauer will immediately turn up in his mind. But, no matter whether he knows much or little about them, it is impossible to enter here into the purely philosophical aspects of their work. All I can say without proof about Kant, Schelling, and Schopenhauer is this. First, their creations are striking examples of autonomous philosophical thought: it would be hopeless to try to link their teaching with the attitudes that may be associated with the class position of the bourgeois or any other element.[8] Second, Kant was the only one of the three to exert significant international influence;[9] but in Germany, all three of them wielded powerful influence upon the thought of generations in whose mental pattern the philosophical component then counted for still more than it did during the subsequent period. Nevertheless, whatever else this influence may have touched or shaped, it did not extend to the professional work of German—let alone of other than German—economists. Many of them no doubt would have described themselves as Kantians. But their professional methods and results were just as compatible with any other philosophy. This question of influence posits itself somewhat differently in the cases of Fichte and Hegel.

Fichte[10] calls for comment, because he associated with his speculative philosophy, in the technical sense of the term, a social and political philosophy that trespassed freely on the economics field and must be noticed for two reasons. He blocked out a plan for a particular economic organization of society that will be considered below in the section on socialism. And he has been assigned a key position in the early development of O. Spann's 'universalist economics.'[11]

---

[8] Some Marxists have tried it, fortified by the conviction that it *must* be possible to do so. Such a conviction will always insure some measure of spurious success that means nothing: everything can be *forced* into correlation with everything else.

[9] Kantian ideas spread in particular to England. Even James Mill grappled with them, but the nonutilitarians, Hamilton especially, and also philosophy-minded divines, put them under heavy obligation, which, considering the elements of English origin that we find in Kant, will not surprise us. A. Marshall's enthusiasm for Kant—highly significant of the intellectual atmosphere of his early days—will be noticed in the appropriate place.

[10] The works of J. G. Fichte (1762-1814) that are particularly relevant to us are his *Reden an die deutsche Nation* (1808), his *Grundlage des Naturrechts* (1796-7), and *Der geschlossene Handelsstaat* (1800), all in his *Sämmtliche Werke* (ed. by I. H. Fichte, 1845-6). Difficulties of interpretation are greatly increased by the fact that his ideas underwent, in several essential respects, changes of two different types: his philosophy changed, in the course of his life, in consequence of his own work upon it; his general outlook changed in consequence of a German's typical experiences during the Napoleonic period that turned the cosmopolitan—who had defined a man's country as that country which happens at any time to stand 'at the height of civilization'—into an ardent patriot.

[11] As has been mentioned already, the idea that the history of economics may be described in terms of the struggle between two 'systems' of thought, an individualist and a universalist one, is really Professor Pribram's. But it was Professor Spann who founded what is known in Germany as the universalist school. On Fichte's relation to it, as conceived by the latter, see O. Spann, *Haupttheorien der Volkswirtschaftslehre*

Fichte was, to be sure, no individualist in the Benthamite sense and no laissez-faire man. If this constitutes a 'universalist,' then he was one, and the only thing to be said is that this species will then grow uncomfortably numerous. If this is not enough to constitute a universalist, we are left with Fichte's conception of a superindividual and 'superconscious' group mind—in which the individual consciousnesses participate. The mere fact that he emphasized the autonomy of the phenomenon Society as against the phenomenon State, besides being as old as scholasticism, has certainly nothing specifically 'universalist' about it. It is true that this conception is in the 'universalist' line, but it is also in many other lines, for example, in the entirely positivist line of Durkheim. Perhaps it is somewhat less unrealistic to assume a connection, via romanticism, between Fichte and Spann than it is to trace Durkheim's thought to Fichte. Confidence in such purely phraseological relations is in any case misplaced and only serves to prevent perception of more substantial ones.

Hegel[12] calls for comment on three counts: first, because of his stupendous success; second, because of his theory of the state and because his philosophy constitutes an important branch of what we shall term evolutionism; third, because of his formative influence on the thought of Karl Marx.

All that I can say about the first point is that it makes Hegel's philosophy one of the factors in the *Zeitgeist* we are trying to survey. More than this I cannot say because the success was beyond anything I might be able to account for. I could explain temporary success in Germany of the philosopher who is credited with the saying: 'Of all my pupils one only has understood me; and this one has misunderstood me.' Perhaps I could also explain, partly by the fact that Hegelian philosophy is capable of widely different interpreta-

---

(1st ed., 1911, many later ones; English trans. 1930). The reader who wishes to have a further and more sympathetic first introduction to universalist economics than I am able to provide is referred, once for all, to Professor Salin's exposition in the *Encyclopaedia of the Social Sciences* (article, 'Economics,' section on 'Romantic and Universalist Economics'), where all the works of Spann are mentioned.

If the reader will carefully go over Professor Salin's exposition (op. cit. vol. v, pp. 386-7), he will immediately see the reason for lack of sympathy on my part. If universalists were content to preach a 'holist' meta-economic or philosophical interpretation of both economic reality and economic theory, there would be no objection; in fact I should actually sympathize with their meta-economics, though I might interpret it to myself in terms of *Gestalt* psychology. In any case, their philosophy would be as irrelevant for us as was Quesnay's theology. But they make larger claims, viz. claims to having developed a new and different method of analysis. They actually 'reject' propositions about pricing and money, for example. And all they do after rejecting them is to reformulate them in a clumsy and inadequate way. For instance, after rejecting the concept of equilibrium, Professor Spann introduced the concept of equi-importance (at margins), which is to do exactly the same things.

[12] G. W. F. Hegel (1770-1831). For us, the most important of his works are: *Phänomenologie des Geistes* (1807; 2nd ed. of English trans. 1931), his most 'realistic' performance that may serve to elucidate some of his more 'abstract' phases; *Wissenschaft der Logik* (1812-16, English trans. 1929) and *Vorlesungen über die Philosophie der Geschichte* (ed. 1837, from lecture notes; rev. English ed. 1899).

tions, why Hegel's influence on German thought not only proved durable but also experienced a strong revival in the twentieth century. But what is beyond my power of comprehension is the great influence he exerted in England, France, Italy, and the United States, that is, on soils that should not have been favorable to this plant. The fact itself is indubitable, however. The second point will be dealt with in section 4 of this chapter. The third, Hegel's influence on Marx, constitutes our immediate concern.

> Many Marxists, and not only those of philosophical bent of mind, have come near to stating that Marxism is rooted in Hegelism and that, the relation being one of dependence, acceptance of the 'dialectic method' constitutes part of Marxist orthodoxy. Marx himself was of a different opinion. In the preface to the second edition of the first volume of *Das Kapital*, he tells us that as a philosopher he had been a Hegelian; that he never lost his early preference for Hegel's philosophy; and that what he considered superficial criticisms of it only served to strengthen his taste for 'coquetting' with it; but that he never allowed himself to be guided by it in his positive research into the facts of capitalist society. I suggest that this statement be accepted. Authors often misinterpret their own procedure and there is the possibility that Marx was mistaken. But it can be shown that he was not. For every proposition of his, economic and sociological, as well as his vision of the capitalist process as a whole, may be either traced to sources other than philosophical—such as Ricardo's economic theory—or else understood as results of strictly empirical analysis of his own. The Hegelism of his exposition is not more than a form that we can discard in all cases without affecting the substance of his argument. The only case that could possibly be considered doubtful will be discussed below.

'Idealistic' (that is, metaphysical) philosophy never ruled unchallenged. As the period wore on, the streak of materialism that we associate with bourgeois rationality asserted itself independently of the utilitarian current. Among other things, it encouraged a materialistic interpretation of Hegel: some people discovered that his metaphysical concepts are not really necessary for his general mode of reasoning, which can stand without them, and dropped them accordingly. Perhaps the most important of the Hegelians who, in doing so, developed into straight materialists was Ludwig Feuerbach.[13] The poor lot of 'free thinkers' (exponents of mechanist or sensationalist materialism), who published in the last decades of that period and are significant only because their popular success was an important sign of the times, owe something to him but less than we might suppose and less than many historians have supposed. Once more: in analyzing broad currents of ideas we are too prone to assume relations between the bubbles that bubble up from the same crater.

---

[13] L. A. Feuerbach's (1804-72) most important work, *Das Wesen des Christenthums* (1841; English trans., 2nd ed., 1877), holds a key position in two respects: first, it attacked the foundations of that part of Hegel's metaphysics that irked its 'free-thinking' followers most, the part that seemed to lend support to religious beliefs; second, it attacked, though less directly, Hegel's metaphysics altogether and turned—a most significant sign of the times—philosophy into a sociology of sorts. (On Marx's violent hostility to Feuerbach's system of thought—that of course does not exclude his being influenced by it—see below, sec. 3c.)

(c) *Comtist Positivism.* Of course, that period's pattern of philosophic thought was very much richer than our survey suggests. But we shall take from it only one more strand that not only embodies another of the main components of that period's *Zeitgeist*, but also is particularly important for economists. In France professional philosophy continued to keep up a Cartesian tradition, curiously interwoven with ideas that hailed from the English empiricists, from Condillac, and, in reaction against Condillac, from Scottish 'common sense.'[14] The antimetaphysical component, which, disregarding any other possible meaning of the word, I shall call *positivist*, asserted itself in many ways. But it found its most nearly adequate expression in a suggestion thrown out by Saint-Simon and carried out by Auguste Comte (1798-1857), a theoretical physicist by training, in his *Cours de philosophie positive*, which was to satisfy two distinct and logically independent needs: first, the need for a general body of thought that would fill the void left by receding metaphysical speculation, the need for a *substitute* for philosophy (or religion); second, the need for a general body of thought that would put some order into the tropical growth of specialized research. Herbert Spencer's *Synthetic Philosophy* —'synthetic' indeed!—that appeared in installments from 1862 on (*First Principles*, *Biology*, *Psychology*, *Sociology*, and *Ethics*) was, in a sense, another attempt to satisfy both needs.

> Comte's *Cours* appeared, 1830-42, in six volumes. Of Comte's other writings only his letters to J. S. Mill (*Lettres d'Auguste Comte à John Stuart Mill*, 1841-1846, publ. 1877) come within our orbit. As regards the rest, the less said the better. It should be kept in mind that, in speaking of Comte and his work, I am referring exclusively to those two publications, for Positivism and Comtism were to acquire also, from the aberrations of his declining years, quite different meanings.
>
> As explained above, the *Cours* presents two aspects which must be carefully distinguished. First, it expounds the doctrine that all our knowledge is knowledge of invariant relations between given phenomena on whose nature or causation there is no sense in speculating. This positivism brought earlier tendencies to a head and anticipated, in some respects, the much more interesting empiriocriticism of the next period. It is a philo-

---

[14] That group is usually referred to, with a value judgment, as eclectics, which perhaps does not do full justice to its most important member, Victor Cousin. It is associated with another group of political theorists and practitioners (and historians) that gathered around the strong personality of Royer-Collard (the 'doctrinaire' party as it was called; Guizot, the historian and prime minister belonged to it—more or less). Both groups are important elements in the Paris picture of the epoch between 1815 and 1848, and their thought displays parallelisms with that of the period's economists. But I can mention them only in order to apologize for my inability to insert them.

sophical doctrine in the technical sense of the term—though a negative one—and as such did not exert, and was incapable of exerting, any influence upon research in any particular science.

But, second, Comte's primary concern was not really with this philosophy. The *Cours* starts with the question how, in an epoch of inevitable specialization, we might salvage that organic unity of all human knowledge that was so vital a reality in the times of the polyhistors. His answer was that we should create for this purpose another specialty, the specialty of *généralités*. This plan has meaning quite independently of whatever philosophic opinions one might entertain and comes to the fore again later on. The *Cours* is an attempt to carry this plan into effect in a particular way and with a particular slant.

Comte's particular way was this: he tried to arrange the total of all scientific knowledge (knowledge from other than scientific sources he did not recognize) into a hierarchy of sciences or, to change the simile, into a building, every floor of which was to be occupied by a different science and which was to rise from foundations in logic and mathematics toward the problems of human society. The six floors were respectively assigned to Mathematics, Astronomy, Physics, Chemistry, Biology, and—Psychology being conspicuous by its absence—Sociology, the science of society. And he actually proceeded, if I may keep to the analogy, to furnish every floor with what he conceived to be those elements in every science that were most important for the science located on the next floor. Nothing can or need be said about the grandeur and the shortcomings of the plan or of its execution.

Comte's influence upon the social sciences in general, and upon economics in particular, was considerable and gathered momentum as the century wore on. This was not because of his 'philosophy,' but because he did sociological work himself. We shall have to touch upon contributions of his—constructive and critical—both in the rest of this chapter and in later chapters. It will be convenient, however, to list the four most important ones, and to dispose of two of them at once: (I) Comte baptized nascent sociology and sketched out a research program for it that foreshadowed later developments in Social Psychology; (II) this sociology is geared, as we shall see, to an eighteenth-century conception of social evolution; (III) he introduced into the social sciences the concepts of Statics and Dynamics; (IV) he developed a methodology that led him to attack the procedure of 'classic' economics in a manner that anticipated many later criticisms. I shall proceed to comment on (III) and (IV).

(III) Comte was primarily concerned with social evolution (see below, sec. 4d). But he fully realized that the idea of evolution does not cover all the problems presented by social organisms. There are also nonevolutionary phenomena or aspects that require a different treatment. Therefore he assembled another body of facts and propositions about 'social instincts,' which act and react upon one another so as to produce by means of an equilibrating process the 'spontaneous order of society'; and this body of facts and propositions he laid alongside the evolutionary compound, or, as he styled it, the theory of 'natural progress.' Adopting, as he tells us, the terminology of the zoologist H. de Blainville, he called the former Statics and the latter Dynamics. J. S. Mill, the author who introduced these terms into economic theory, was well acquainted with Comte's thought, and it is natural to assume that he took them from Comte, though he did not say so. If this was the case, then Mill was wrong in speaking (*Principles*, Book IV, ch. 1) of 'a happy generalization of a mathematical phrase.' Since many people who failed to appreciate the importance of that distinction have tried to stigmatize it as an illegitimate derivate of a mechanistic way of thinking, it is time to state the fact that, so far as there is sense at all in talking about borrowing—as regards the words that is, not as regards the distinction itself which forces itself upon us in any case—the ultimate lender was not mechanics but zoology. We shall return to the subject more than once. It should, however, be mentioned that Mill's definitions of statics and dynamics correspond to Comte's, as far as I can see; but these terms subsequently acquired several different senses and are now being used in a still different one.

(IV) Methodologically, Comte's plan was to observe historical and ethnological facts and to build his science of society from such generalizations as these facts would suggest. This is, of course, a very familiar program that was, then and later, espoused by numerous writers, especially by historical economists. All the more important is it to realize a paradoxical fact: while it was perfectly natural for historical economists to adopt this plan, it was not at all natural for Comte to do so. The historian, and hence the historical economist, distrusts any theory that tries to 'isolate' the economic element in social life. Theory is for him indeed speculative and unrealistic. It is even something still worse: it is speculative construction that borrows its methods from the physical sciences. Only the real phenomenon in *all* its historical facets—with the economic, ethical, legal, and cultural facets all simultaneously considered—is for him the true object of social research, whose methods must therefore differ *toto cælo* from any used by the physicist. But Comte could not argue like this. On the contrary, he wanted to adopt the methods of the physicist. When *he* accused 'classic' economists of unscientific speculation, he meant exactly the opposite of what the economists of the historical school were to mean. And there, as J. S. Mill realized, he was completely in error. But in addition to being in error as regards his criticism, he was also in error as regards his own choice of method. For physical science does not accept unanalyzed fact: either in the laboratory or (where laboratory experiment is not possible) by mental experiment, physicists do separate or isolate individual aspects and then theorize about them with a boldness that far surpasses anything that economists ever ventured to do. Had Comte wished to be 'scientific' in *this* sense, he could not have adopted any method other than that followed by Bentham, Say, and later by J. S. Mill. He adopted the one he did adopt (generalization from unanalyzed historical or ethnological fact) by mistake and, if he anticipated some of the later arguments of the historical school, he anticipated them, again, by mistake—honest ignorance of economics and Saint-Simonian prejudice against it being, of course, the psychological sources of both. The comedy of errors will be complete when we realize that, on top of it all, he indulged in *genuinely* metaphysical speculation himself. This clarification reduces considerably our conception of Comte's influence: the later historical economists of the Schmoller school were not Comtists at all; their philosophical and methodological affiliations were quite different; they arrived at their arguments against 'classic' theory from the logic of their own intellectual position and would have arrived at them even if Comte had never lived; it is merely a coincidence that, as it was, these arguments, or some of them, look Comtist to the historian.[15] With other exponents of historicism, Comte's influence is more in evidence. (On Ingram, for example, see below, Part IV, ch. 4.)

2. ROMANTICISM AND HISTORIOGRAPHY

We might learn a lot about the *Zeitgeist* from surveying the literary currents of that period were it possible to do so. Very interesting inferences could be drawn, for example, from the success of the novels of Dickens, Thackeray, or Flaubert, which are also really sociological treatises—highly colored by ideologies that we do not usually attribute to the people who read them. Or to mention but one other and far distant example, we might also learn a lot by analyzing the burst of German enthusiasm for Greek art that started in the eighteenth century[1] but survived well into the nineteenth. We must refrain. But there was one literary movement, Romanticism, that we cannot afford to pass by, partly because of its real importance for the development of the social sciences, partly because of the importance that has been wrongly attributed to it.

(a) *Romanticism.* Like its cultural antipode, utilitarianism, the romantic movement started in the eighteenth century: we, who are primarily interested in its analytic performance, cannot do better than to choose as our landmark the great name of Herder.[2] Unlike utilitarianism, romanticism was not a philosophy, or a social creed, or a political or economic 'system.' It was essentially a literary fashion that linked up with a certain attitude toward life and art: on the one hand, the movement was entirely confined to intellectual circles—there are no romanticists who were not also literati; on the other hand, the movement gained international importance primarily in the field of belles lettres and in the neighboring fields of literary criticism and philology. For painting, architecture, and music it meant less—though it also set fashions there, witness, for example, some 'Gothic' horrors—and it influenced but peripherically whatever else it touched. But from the history of literature it is indeed possible to compile an impressive list of names, such as Byron, Alfieri, Shelley, Wordsworth, Coleridge, Scott, Longfellow, Chateaubriand, Gautier, Hugo, Hölderlin, Novalis, Brentano, Arnim, and the two Schlegels.[3] It is there that we must look for the achievement of romanticism and for the serious work of the romanticists. They no doubt sallied forth from that stronghold, as literati will, and roamed all over those parts of philosophy and social science that happened to attract them. It is with their exploits on these excursions that we are concerned here. But we must bear in mind that in dealing with these we are not dealing with the core of romanticist achievement and that we must expect any grain we may find to be mixed with dilettantic chaff.

---

[15] This is not true for sociology: many sociologists, especially French ones, did descend from Comte (de Roberty, Durkheim, and others). But as regards the economists who faced each other in the Battle of Methods, Menger, the theorist, was much more Comtist than was Schmoller, the historian.

[1] J. J. Winckelmann's *Geschichte der Kunst des Altertums,* a book, both symptomatically and causally important, appeared in 1764.

[2] J. G. von Herder (1744-1803): *Fragmente über die neuere deutsche Litteratur* (1767), the most definitely romanticist of his works; *Über den Ursprung der Sprache* (1772); *Ideen zur Philosophie der Geschichte der Menschheit* (1784-91), for us the most important of his writings. But Herder's thought transcends romanticism: influence from and influence on romanticism is but one aspect of his work. As a sociol-

However, even as regards belles lettres we cannot help being struck by a fact that is indeed evident from our little list of names and would stand out still more clearly in any more extended one: works and men that in one sense or another may be labeled romanticist often have very little in common and look strange in juxtaposition. This will cease to surprise us as soon as we make an attempt to define what the romanticist attitude consisted in. On the surface, it spelled revolt against classic canons of art, for instance, against Aristotle's three dramatic unities (of time, place, and action). But below this surface, there was something much more important, namely, revolt against convention, particularly against rationalized convention: feeling (possibly genuine) rose against cold reason; spontaneous impulse against ultilitarian logic; intuition against analysis; the 'soul' against the intellect; the romance of national history against the artefacts of the Enlightenment. Let us call this attitude anti-intellectualism, although this term will also be used in a different sense below. Remembering that the romantic movement was confined to in-

---

ogist he also experienced and exerted influence of an environmentalist type (see below, sec. 3c); he fought Kant's aesthetics in an almost empiricist spirit, and there are passages in his *Ideen* on cultural change that have a Spencerian ring; his theories of language, literature, art, religion, mythology—including the methodological suggestions in the direction of comparative philology and comparative mythology and hierology—make him the precursor of several important modern, as they make him the heir to several important eighteenth-century, tendencies, including tendencies enshrined in the Hobbes-Locke-Hume tradition. If we cannot go into these cross currents of ideas that elucidate many features of the nineteenth-century *Zeitgeist*, our comfort must be that they entirely failed to fertilize economics.

[3] Goethe is too great to be pigeonholed and, moreover, disliked the romanticists intensely. But his work, both at dawn and at sunset, displays many romanticist elements. It is only in between that Goethe was, or tried to be, severely 'classic.'

tellectuals—and therefore was something quite different from what we may term the common man's anti-intellectualism—we should not flinch at the apparently *paradoxical designation, intellectual* anti-intellectualism. Viewed like this, the phenomenon of romanticism really comes within a well-known class: like other workmen, intellectuals seem from time to time to get disgusted with their tools and to be possessed with a desire to 'down' them and to use their fists instead.

This diagnosis explains, among other things, why it is impossible to systematize romanticism into a coherent whole and to develop rules that would enable us to identify romanticist ideas or programs as easily as we can identify, for example, utilitarian ideas or programs. The movement was in the nature of a shake-up. Its fertility was principally due to this fact. The individual who experienced its impact was left free to walk in any direction after having been shaken up. This applies particularly to the political and economic views of individual romanticists which later historians have tried to unify in directions of which they themselves approved if they were sympathetic, and in directions of which they disapproved if they were hostile. The resulting picture was unrealistic in both cases. Romanticism has been identified with political 'reaction'; it is true that many romanticists, following the tendencies of their time, turned conservative or 'reactionary' when their environments did, and that some of them even sold their services to 'reactionary' governments; but the essentially revolutionary character of the movement was never quite lost, as may be gathered from the case of that powerful leader of opinion, Joseph von Görres. Romanticist ideology has been contrasted with Benthamite ideas about liberty and democracy; again it is true that romanticist liberty was not the liberty of J. S. Mill's essay and that romanticist democracy was not Bentham's mechanistic thing; but it might be urged that some romanticists had a deeper understanding of what liberty and democracy meant to people *as they are and think and feel* than had the utilitarians or than has anyone who tries to impose a logical scheme of his making on existing social patterns. Romanticism has also been credited with a strong taste—taste is the right word, since we are speaking of literati—for the Roman Catholic faith; it is true that the romanticists, with their sense for live realities, were bound to look upon that mighty structure with feelings very different from those of the utilitarians; it is also true that, at least in the early nineteenth century, their movement went parallel with and was related to, a Catholic revival; but it is quite wrong to confuse the two. Few of the true leaders of the Catholic movement (Görres is the most important instance, Chateaubriand a doubtful one) were prominent in the romantic movement; most of them stood to it on a footing of cool and reciprocated indifference. Finally, if romanticism has been associated with 'universalist' social philosophies, this was only because romanticists were opposed to rationalist individualism of the utilitarian type; but the feeling, the intuition, the impulse they extolled were subjective and *individual* feeling, intuition, and impulse—this extreme subjectivism, which knew no binding rule, was precisely what set Goethe against them.

What, the reader may well ask, can have been contributed to economics by a movement such as this? The answer will, of course, read differently according to whether we think of attitudes to practical problems, ideological haloes, humors, and so on, or of technical analysis. A romanticist or any writer influenced by the romantic attitude would, of course, look upon industrial life and its problems in a nonbourgeois spirit and take views quite different from the Benthamite ones. More generally, he would feel a healthy disgust at the utilitarian tendency to reduce the colorful variety of social patterns and processes to a few bald generalizations about thoroughly rationalized hedonic interests. And he would build where utilitarianism leaves a void—or else provides a dump for what is simply nonsense from its standpoint—a shrine for the historically unique and for the values of the extrarational (though, as the discussion above shows, these values differed greatly from one romanticist to another). As voiced by some romanticist writers, much of this does not quite ring true. It should be clear, however, that not all of it was literary fake. The standpoint that is appropriate for a history of the search for scientific truth is not appropriate for a comprehensive appraisal. Nevertheless, we may list definite contributions to positive analysis.

There are *none* to be recorded so far as technical economics is concerned. Considering the nature of the movement, this is only what we should expect and does not even amount to a criticism. Enthusiastic lovers of romanticism seem to me to have committed a tactical mistake by insisting on the presence of contributions of this nature, especially because it forced them to make a hero of such a man as Adam Müller (1779-1829). As far as this goes, it should be frankly admitted that there never was such a thing as a 'romantic school of economics' at all.

It was, I think, W. Roscher who gave currency to that phrase by his paper, 'Die romantische Schule der Nationalökonomik in Deutschland,' *Zeitschrift für die gesamte Staatswissenschaft*, 1870, and who covered Müller with unmerited praise. Modern 'universalists,' having been hard put to it to find other members for this 'school,' have resorted to three devices: first, they included men such as F. Gentz and K. L. von Haller (the interested reader is invited to look them up in any work of reference), who were no economists at all; second, they claimed for the school famous men who had but the most tenuous relation to it, if indeed any, such as F. List; third, they applied themselves to the task of unearthing additional members who were duly dubbed geniuses, such as Franz von Baader (*Sozietätsphilosophie*, in his *Sämtliche Werke*, 1854), who may pass for a sociologist. As to Adam Müller himself (mainly: *Elemente der Staatskunst*, 1809, new ed., 1922; *Versuche einer neuen Theorie des Geldes . . .*, 1816, new ed., 1922; *Von der Notwendigkeit einer theologischen Grundlage der gesamten Staatswissenschaften*, 1819; a selection of papers has been edited by Dr. Jacob Baxa, who also wrote a life of Müller with complete bibliography, 1930), it is sufficient to state that his economics consists in a negative revaluation of part of A. Smith's facts and arguments—of laissez-faire, free trade, division of labor, and so on—which is his and not our affair, and in the introduction of a number of wholly inoperative metaphysical conceptions.

Suppose even that there is any sense in saying, for instance, that money is money only in the moment it changes hands and that in this moment it is not private (*allod*, as he called it) but public property (*feod*), or that it is the expression of 'national value' or 'national force'—what of it? Such interpretations of metaphysical meanings are by nature incapable of telling us anything that we do not already know about the relations subsisting in the empirical world. On the other hand, I do not wish to go further than this. I have no intention of paralleling the ignorance that fails to appreciate the tasks and methods of analysis by equally ignorant failure to appreciate the tasks and methods of philosophic vision or interpretation of meanings. It is enough for me if I can make the reader understand that these are two different worlds that do not touch anywhere and neither of which can tell us anything about the phenomena —or whatever the word should be—in the other without reducing its own arguments to futility. In order to make this point stand out strongly, I refrain from asking the question how good or bad A. Müller's speculations are when considered as philosophics.[4]

It seems possible, however, to speak of a romanticist sociology or at least of definite contributions of romanticist writers to economic, political, and general sociology. One has been mentioned already: we may restate it by saying that it consists in the insertion, into the analysis of institutions and of behavior within institutions, of the compound of nonrational—not necessarily irrational—human volitions, habits, beliefs, and so on, which largely make a given society what it is and without which a society and its pattern of reaction cannot be understood. The names of Herder and Novalis[5] may be mentioned as illustrations. The artistic component in romanticism is, in particular, responsible for emphasis upon psychological relations and reactions, a fact which lends some color to the view that the romanticists were forerunners of modern social psychology.[6] The outstanding example of contributions of this kind are the concepts of a National Soul (*Volksseele*), a National Character, and a National Fate. Such concepts came readily to literati and they acquired with them an emotional connotation. But the sentiments, as well as any philosophical visions, may be dropped, whereupon the National Soul reveals itself as a catch-all for a number of very important facts. Even as an entity it has appealed to many later sociologists of the group-mind type. How very 'positive' a thing can be made of it is shown by the fact that we also find it in so thoroughly unromanticist a writer as Comte.

But the chief importance of the romanticist movement for analytic economics consists in the impulse it gave to all kinds of historical research. It taught us better understanding of civilizations other than our own—the Middle Ages, for example, and extra-European cultural worlds as well. This meant new vistas, wider horizons, fresh problems, and, above all, the end of the stupid contempt that Voltairians and utilitarians professed for everything that preceded 'this enlightened age.'[7] Let us glance at the most important of the cases where romanticist influence, national soul and all, shows unmistakably, on the surface at least: the emergence of the Historical School of Jurisprudence. This school acquires additional significance for us because it helped to produce a similar movement in economics.[8]

---

[4] It is on this question only that meaningful difference of opinion is possible between us and the modern universalist admirers of A. Müller. And with this statement they should really agree—especially as I am also prepared to concede political value judgments—because they have always affected to despise the field for which I claim autonomy from romantic or any other metaphysical speculation.

[5] Novalis was the pseudonym of Friedrich von Hardenberg (1772-1801), German poet. A fragmentary theory of society may be compiled from his unsystematized writing (*Gesammelte Schriften*, ed. Obenauer, 1925). There is an essay on him by Carlyle, which does not, however, go much beyond artistic aspects.

[6] I do not share this view without qualification (see below, Part IV, ch. 3, sec. 3e).

After the Wars of Liberation, national exhilaration asserted itself in many proposals that, more or less directly, pointed toward a unified Germany. Among them were proposals for codifying the German law. One of these—by a prominent jurist, Thibaut—was adversely criticized in a pamphlet by Savigny that attracted nationwide attention.[9] Its argument rose high above the particular occasion and amounts to a general sociology of law: the legal institutions of a nation are part of its individual life as a nation and the expression of the whole of it, and of the whole of its historically determined situation; they embody all the intimate relations and necessities of this life which find in them more or less adequate formulation; they fit as does the skin of the human body; to replace them by a rationally excogitated code is like tearing off a body's skin in order to replace it by a synthetic product. Hence—this is what matters to us—the necessity of studying law not from the standpoint of a few rational principles, but within the framework of all its bearings on the national soul or character. Hence the conclusion—in exact opposition to the

---

[7] Théophile Gautier occasionally used the phrase *moyennagiste* as a synonym for romanticist, and the two phrases seem in fact to have meant much the same for the whole romanticist *cénacle* in Paris. This cult of medieval civilization did not fail, of course, to elicit liberalist sneers, the more so because it involved unhistorical idealizations as well as (in the case of Gautier) red waistcoats. But we must see through and condone the inevitable pranks of literati: if ignorance entered into this cult, much more ignorance had entered into that of *la raison*.

[8] The influence of the historical school of jurisprudence is particularly evident in the case of Roscher, who took arguments from the jurists and attached importance to what he considered to be a close parallelism between the situations in the legal and the economic fields. In other cases, that of R. Jones for instance (see below, ch. 6), no such influence can be proved.

[9] *Vom Beruf unserer Zeit für Gesetzgebung und Rechtswissenschaft* (1814), by Friedrich Karl von Savigny (1779-1861), an academic jurist of established reputation, who had, by an earlier work of striking originality (*Recht des Besitzes*, 1803), rejuvenated the decadent jurisprudence of his day. By the foundation, with Eichhorn (who represents the Germanist element in the alliance, as Savigny represents the Romanist), of the *Zeitschrift für geschichtliche Rechtswissenschaft* (1815), by his *Geschichte des römischen Rechts im Mittelalter* (1815-31), and by his *System des heutigen römischen Rechts* (1840-49), he rose to a position of recognized leadership in the German legal world of his day, both in the academic and (in Prussia) in the official sense. This leadership meant the victory, for the time being, of the historical school. But he should not be called its 'founder.' As could be shown had we space, he brilliantly led and developed a tendency, all the seeds of which had been sown before.

Benthamite view—that the only method for scientific jurisprudence to pursue is the historical one.[10] This, in a nutshell, was the creed and program of the historical school of jurisprudence. Owing to the use of the concept of a national soul and character, the relation between this historical sociology of law and specifically romanticist thought stands out strongly, perhaps more strongly than it should. For common sense tells us that there would have been historical jurisprudence even if there had not been any romanticism. This also applies to those German economists who, having undergone legal training or having what by a later American term we may call an institutionalist bent, were no doubt influenced by the example of the historical school of jurisprudence.

(b) *Historiography.* The extent to which the rich developments in that period's professional historiography are to be credited to romanticist ideas is still more debatable. It is true that the romanticist mood stimulated interest in historical research and increased the public's receptiveness to its results. Beyond this it is not safe to go without more specific reasons than a general belief in the all-pervading influence of romanticism. But it seems to me that one such reason does in fact exist. The period had indeed a large number of historians who pleaded a cause, the cause of a country or of a political system or a party, or made it their business to grade—yes, as a schoolmaster grades his pupil's books—the men and events reported on, according to moral or cultural standards of their own.[11] A tendency toward taking a different line asserted itself, however: to present facts in their own light, to let events appear as they might have appeared to the people who experienced them, to preserve the color and the spirit of time and place. This 'immanent interpretation' of historical processes evidently raises very serious methodological problems as regards the nature of the intuitive understanding of the individuals and civilizations it involves. For us it is of particular interest because of the close affinity of its principles to those of Max Weber. It is primarily associated with the name of Leopold von Ranke.[12] A French sponsor of it was Augustin Thierry. The work of these and other men was, in its scholarly aspects, neutral to romanticism and, in other aspects, even hostile to it. But their respect for the autonomy of every culture and for its individual color constitutes an affinity with romanticist ideas that we must not overlook.

---

[10] These points must be kept in mind if misunderstanding is to be avoided: (1) This sociology of law is *not* quietist or hostile to reform. It only sponsors 'organic' reform from 'organic' necessities as against reform from speculative principles. Savigny himself, as Grand Chancellor, carried reforms. (2) This sociology, by virtue of its emphasis upon historically given conditions, has a side that might be described as 'national.' But it has no 'nationalistic' implications whatsoever. (3) Even reforms carried out in the historical spirit presuppose certain general principles and deductions from them. Savigny overlooked this and his program was therefore, however great its merits, scientifically inadequate. From our standpoint as economists, it is very important, on the one hand, to notice this error and, on the other hand, to realize that it does not necessarily impair the usefulness of the historical method.

[11] Thus, Lord Macaulay pleaded the causes not only of England, but also of the Whig party: he made no effort to understand any other standpoints. Michelet glorified France; Droysen, Prussian policy; Dahlmann and von Rotteck pleaded for liberalism and constitutionalism; Grote for Athenian democracy (George Grote, *History of Greece,* 1st ed., 1846-56, is of particular interest to us because he was an orthodox Benthamite and one of the most important members of the philosophical-radical circle); G. Bancroft for Jacksonian democracy. In all such cases there is, irrespective of any conscious intention of the authors, obvious danger of ideological distortion of facts. But even if all facts are reported with scrupulous impartiality, they will still stand, as it were, in an artificial light—the light of the writer's convictions or creed—and not in their own. Consider an additional example of a somewhat different type: W. E. H. Lecky (especially *History of the Rise and Influence of the Spirit of Rationalism in Europe,* 1865), one of the relatively few nineteenth-century exponents of the eighteenth-century *raison.* To begin with, he wrote from a definite sociology of history that makes ideas the prime movers of the historical process. In addition, he re-

For the rest, since it is impossible to report on that period's historiography so as to convey an adequate impression, we must confine ourselves to a brief survey of those features of it that are most relevant for economics. In the first place, there were the new materials and the new standards of criticism. It was during this period that historiography definitely stepped out of the range of literary sources and—systematically and on a large scale—began to use original documents and the information that is enshrined in monuments, inscriptions, coins, and the like. Cuneiform writing (Grotefend) and hieroglyphs (Champollion) yielded their secrets. Techniques for the exploitation of source materials were taught, and comprehensive publications of such materials were undertaken: the École des Chartes, the English Rolls Series, and the *Monumenta germaniae historica* are examples of a purposeful and systematic activity, for which there was no parallel in our own field. Criticism of sources attained new levels, and it was this plus the new materials that produced the achieve-

---

duced the march of ideas to a scheme that is unaware of anything but an increasingly successful struggle of reason with religion. He thus produced a report that stands and falls with a definite creed and has no meaning irrespective of it. I use this opportunity to advert to the problems that arise from the naïve habit of historians who have no axe to grind or cause to plead but set themselves up as judges of all things human, who know all motives and are in possession of all standards of behavior. An example will illustrate. The great Mommsen was a conspicuous victim of the self-delusion involved: he knew how the Roman legions should have been handled in the battle on the Trebbia; he knew how Cicero ought to have dealt with Catilina's conspiracy; he knew what motives swayed Julius Caesar. He never displayed any awareness of the dangerous extent to which he relied on his intuitive comprehension—the comprehension of a no doubt able and respectable middle-nineteenth-century bourgeois mind. This has some obvious bearings also upon procedures of economists.

[12] Without presuming to proffer my own opinion, I may state that a majority of historians of all countries would agree to call him the first historian of that period. His international influence—also on historiography in the United States—rests mainly on the new standard of historical scholarship that his famous seminar was the means of establishing. His mastery in exploiting new source material and in applying new canons of criticism was of a piece with his refusal to accept the guidance of philosophical (especially Hegelian) ideas. If we notice the romanticist element in his work, it should be added that he himself was careful to distance himself from romanticism.

ments of Niebuhr[13] and Mommsen. But the emphasis upon the original document was quite general. It constitutes the main *scholarly* merit of Michelet. We find it also in writers whom we do not value primarily as scholars, for example, Thiers, the politician. We find it even in the creators of the realistic novel, for example, the brothers Goncourt.

In the second place, historians developed a bent for sociological analysis that benefited from its proximity to facts. Niebuhr's attention to institutions and to the question of the effects of policies and reforms and Thierry's attention to racial factors may serve as examples. This hardly ever amounted to explicit theorizing, but it very often implied sociological theories though, needless to say, they were none the better for not being properly articulated. Moreover, much more than before, we observe interest in economic phenomena per se. This interest manifested itself even where we should least expect it, in the field of ancient history,[14] on the one hand, and in the 'pictorial' history of the period, on the other. Lord Macaulay's *History of England* (1848-61) illustrates to perfection what I mean by pictorial history—history that concentrates on the picturesque military or political events and narrates them with an eye to stirring effect. But Macaulay has chapters descriptive of economic and social conditions that are indeed effective pictures but entirely different ones. An analogous statement holds for L. A. Thiers' *History of the French Revolution* (1st French ed., 1823-7; English trans. 1838).

In the third place, there was a literature, important by virtue of achievement but still more important as the basis of later developments, that may be described as the product of the purely scientific wing of the historical school of jurisprudence or as the product of the institutionalist wing of the historians. I shall illustrate this by the names of four eminent men whose lines of research, widely though they differed from one another, all come within the category envisaged. Maurer[15] was the leading though not unchallenged authority on the social organization of medieval Germany, and his theories exerted influence far and wide throughout the nineteenth century—even after they had become obsolete. Fustel de Coulanges' famous book, which penetrated into the general reading of the educated (but not, so far as I can see, into that of economists), arranged the fruits of scholarly work around a theory to the effect that religion is the most important factor in shaping the legal and political institutions of a society, a theory that, owing to the close correlation between the various departments of national life, will never be contradicted by facts, even though it should be wrong or inadequate.[16] Sir Henry Maine's (1822-88) leadership belongs to the next period, but the work that spread his fame belongs to this. It presents a most instructive piece of a historian's theorizing.[17] Finally, the historico-ethnological work of J. J. Bachofen [18] must be mentioned, though its influence also belongs in the next period.

---

[13] I wish I could stay to sketch the personality and work of this civil servant, scholar, banker, teacher, and ambassador (B. G. Niebuhr, 1776-1831), whose *Römische Geschichte* (1811-32) placed research in Roman history on a new footing. Among other things, he holds two claims to being considered an economist also: he was an authority on currency policy; he wrote *Forschungen zur internationalen Finanz- und Bankgeschichte* (A. Trende ed., 1929). Theodor Mommsen's famous *Römische Geschichte* appeared 1854-6.

[14] Examples are, *Die Staatshaushaltung der Athener*, a study of Athenian finance by August Böckh (1817) and, still more significant, the *Ideen über die Politik, den Verkehr, und den Handel der vornehmsten Völker der alten Welt* (1793-1812, English trans. 1833-4) by A. H. L. Heeren. The influence of this great scholar and teacher extended over a wide domain that also included political geography.

[15] G. L. von Maurer (1790-1872), *Geschichte der Markenverfassung in Deutschland* (1856); *Geschichte der . . . Hofverfassung in Deutschland* (1862-3); *Geschichte der Dorfverfassung in Deutschland* (1865-6); *Geschichte der Städteverfassung in Deutschland* (1869-71).

Finally, in the fourth place, *Kulturgeschichte*,[19] though not of course a new phenomenon, established itself as a recognized specialty. Its bearings upon our subject are obvious. It may paint murals or it may paint miniatures. The footnote below mentions the outstanding masters of the two forms, Burckhardt and Riehl.[20]

---

[16] N. D. Fustel de Coulanges (1830-89), *La Cité antique* (mainly the Greek city state or *polis*), 1864; English trans. 1874.

[17] Sir Henry Maine, *Ancient Law* (1861). Students of economics should know more about Maine's work than the slogan 'from status to contract.'

[18] That is, the one work of Bachofen's that I shall mention: *Mutterrecht* (1861), the fountainhead of a whole literature on matriarchy.

[19] Another word that is refractory to translation except by the un-English phrase, history of culture. History of civilization is not quite right. History of civil society would be still more misleading.

[20] Of Jakob Burckhardt's (1818-97) imposing works, it will suffice, for our purpose, to mention *Die Kultur der Renaissance* (1860; English trans. 1878). The nature of the performance, which I trust is familiar to every reader, is difficult to define in general terms. Perhaps this phrase will come as near to defining it as it is within my power: a vision of an epoch's life in terms of art and politics (both taken in the widest possible sense). The essential point that differentiates such a structure from the history of any of the things that furnish the material for it—from the history of art and literature per se, or science per se, or economic, social, or any other politics per se—is that these things do not stand in the structure for their own sake, but for the sake of expressing, *functionally*, some larger and deeper reality. Jakob Burckhardt's place in the history of thought transcends this performance, and the influences (Ranke's among them) that helped to form him and the influences that emanated from him would be interesting to analyze. But the popularity of the work I mentioned must not deceive us concerning his influence as a social philosopher or political thinker. He was too far removed from the liberal slogans of his time and then again too far removed from any prophetic wrath about them to wield much influence.

W. H. Riehl (1823-97) might have been included in the next section's report. For his work is still more definitely relevant to professional sociology than is Burckhardt's. But the elements of his sociology (some of them anything but bombproof) would have to be picked out from what, fortunately, always remained *historical* work. I do not think that his influence went much beyond Germany's frontiers. But perusal of his *Kulturstudien aus drei Jahrhunderten* (1859) would do a lot of good to students of economics. This book might be an excellent substitute for some of the items on our current reading lists.

3. SOCIOLOGY AND POLITICAL SCIENCE: ENVIRONMENTALISM

We know that sociology dates from the scholastics and even from the Greeks. But the status of a recognized field of research it did not acquire before the next period (see Part IV, ch. 3). In the period under discussion sociology was indeed, as we have put it above, baptized by Comte, but no great importance should be attributed to this fact. It is true that there was plenty of important sociological work. But it remained unco-ordinated and unsystematized. Most of it we have noticed already. We may speak of a philosopher's sociology, a lawyer's sociology, a historian's sociology. Each of them took many forms that differ widely from, and stand in the most varied relations to, one another. It is dangerous to force these forms into large categories. But, for the purpose of a summary review, they may be divided into an 'abstract' and a 'historical' compound. In practical importance, Benthamite utilitarianism stands first among the former,[1] historical jurisprudence first among the latter. In this section we shall adopt, as far as possible, this schema. In addition an attempt will be made to supplement our sociological harvest by whatever we can glean from the period's literature on government and politics, for which the phrase Political Science then came increasingly into use, and by a brief glance at a line of thought that should interest economists particularly, Environmentalism.

(a) *The Natural-Law Sociology of Government and Politics.* Let us recall three results that have been established previously at various turns of our way. First, the historical origin of all social science is in the concept of Natural Law, which was from very early stages associated with more or less definite concepts of 'community' or 'society.' The Greeks *may* have confused the latter with the concept of government. It would have been natural for them to do so under the conditions of the *polis*. But the scholastic doctors were proof against this analytic mistake, because the practical problems of their age and their own position in the social organism could not fail to make it clear to them that the State or the Government—or the 'Prince'—is a distinct agent with interests of its own that do not necessarily coincide with the interests of the people or the community (the Common Good). That 'society' was a discovery of the philosophers of natural law, of the romanticists, or of still later groups is one of the legends of the history of sociology.[2] Second, we have seen that utilitarianism was a natural-law system. Like all natural-law systems, it was all-embracing in principle and very nearly so in actual practice. It was conceived as a unitary social science that was both normative and analytic and, among other things, included ethics, government, and legal institutions down to all the details of judicial procedure and criminological practice—in both of which Bentham himself was at least as intensely interested as he was in any economic question. Third, we know that this unitary social science of utilitarianism was individualist, empiricist, and 'rationalist,' the last term meaning here simply that the system, both in its analytic and in its normative aspects, strictly excluded everything that would not pass the test of utilitarian or hedonist rationality. The reader will save himself much trouble and greatly improve his understanding of doctrinal history if he gives due consideration to two vital facts. First, individualism does not necessarily involve empiricism or rationalism in this sense;[3] empiricism does not necessarily involve individualism and rationalism in this sense; and rationalism in this sense does not necessarily involve individualism and empiricism. But, second, so powerful a synthesis as Bentham's was bound to create, in the minds of foes as well as friends, an association between all the elements that enter into it which gave the impression of logical connection even where none existed.[4]

---

[1] Other types of sociologies, or fragments of sociologies, that were abstract in the sense that they proceeded from a few 'first principles,' are to be found chiefly in the writings of speculative philosophers. Thus, Kant presented what he described as Metaphysical Elements (*Anfangsgründe*) of the Theory of Law (*Werke* IX, pp. 72 et seq.). This theory was 'abstract' and nonhistorical enough. But it was, of course, anything but utilitarian.

[2] If there is a writer who actually can be accused of confusing the State with Society, that writer is the romanticist A. Müller, for he called the state the 'totality of human affairs' (*Elemente*, vol. I, p. 60).

Now, by virtue of its very nature, this system is incapable of taking account of the facts of political life and of the way in which states, governments, parties, and bureaucracies actually work. We have seen that its fundamental preconceptions do little harm in fields such as that part of economics where its 'logic of stable and barn' may be considered as a tolerable expression of actual tendencies. But its application to political fact spells unempirical and unscientific disregard of the essence—the very logic—of political structures and mechanisms, and cannot produce anything but wishful daydreams and not very inspiring ones at that. The freely voting rational citizen, conscious of his (long-run) interests, and the representative who acts in obedience to them, the government that expresses these volitions—is this not the perfect example of a nursery tale? Accordingly, we shall expect no contributions to a serviceable sociology of politics from this source. And this expectation is almost pathetically verified. Strong common sense redeems, to some extent, Bentham's philosophy of government as presented in the *Fragment on Government* (1776) and, of course, very many of his practical recommendations on judicial procedure and the like. But James Mill's 'Essay on Government'[5] can be described only as unrelieved nonsense though, so it seems, also ineradicable nonsense. Moreover, its purely speculative character—so unlike the character of the same author's no doubt abstract argument in his book on economic theory[6]—is obvious. This was realized at the time by many non-utilitarians such as Macaulay. But much more important is it that J. S. Mill (without mentioning his father's name) applied to the political theory of the Benthamite school the unflinching epithet 'unscientific' (*Logic*, VI, ch. 8, § 3) and that in addition, his sentences vibrating with suppressed impatience, he said practically everything else that needs to be said about it. In this, as in so many respects, he rose above his early Benthamism. But he never shook off its shackles entirely: though his essays *On Liberty* and *Considerations on Representative Government* are no doubt redeemed, in part, by wider horizons and deeper insight, they are still 'philosophical radicalism.' It will thus remain forever a matter of the historian's personal equation whether J. S. Mill's theory spells abandonment or improvement of that of his father.[7]

---

[3] This sense of the term rationalism has, of course, nothing to do with the sense which we attributed to it in another place (II, ch. 1, sec. 6). But all along, these two and other meanings have been confused by many writers—a fertile source of mutual misunderstandings and of pointless antagonisms and controversies.

[4] Actually, the situation was and is further complicated by the fact that, of the terms mentioned, only 'empiricist' (in the sense of antimetaphysical) has a fairly stable meaning. The preceding footnote shows that this is not so in the case of 'rational' or 'rationalistic.' The case of the term 'individualism' is still worse.

[5] *Encyclopaedia Britannica* (suppl., 1823).

Non-utilitarian and anti-utilitarian philosophers also continued to produce systems of natural law—and corresponding philosophies of the state—but of much more restricted scope, most of which reflect the influence of the romantic mood or else the influence of Kant or Hegel.[8] The harvest to be gathered for our purposes from this field is small indeed. Lawyers, too, continued to produce natural-law speculations. The most valuable ones were, however, in special fields, such as constitutional or criminal law.[9] More comprehensive enterprise of this type was being rapidly discouraged by the rising prestige of the historical school.[10] An extremely influential performance of this kind, Stahl's, must however be noticed.[11] For the rest, lecturers displayed a significant tendency to turn their lectures on philosophy of law into lectures on the *history* of the philosophy of law.[12]

---

[6] After all that has been said above, the difference should be obvious. But the point is important both for our immediate object, which is to show why general objections against utilitarian premisses do not necessarily constitute objections in the particular case of economic theory, and for our wider aim, which is to understand why general objections against any philosophy do not in themselves dispose of any particular theory that, actually or apparently, links up with that philosophy. Therefore, let me restate the argument in still a different form: any theory involves *abstractions* and therefore will never fit reality exactly, hence economic theory is inevitably unrealistic *in this sense*; but its premisses are induced from realistic observation of the profit-seeking and calculating businessman; the premisses of political theory (style James Mill) are not induced from observations of the agent of politics, the politician, but *postulated* from a completely imaginary agent, the rational voter; therefore these premisses, hence results that are derived from them, are not merely abstract but also unrealistic *in a different sense.*

[7] Exactly as in the case of the theory of value, as we shall see more fully later on; in all parts of his wide domain, J. S. Mill's intellectual situation and character asserted themselves in precisely the same way.

[8] A fairly long list, chiefly of German performances—for England, T. H. Green's would have to be mentioned—could be compiled. We merely recall one of the earliest and most influential that has been mentioned already, Fichte's *Grundlage des Naturrechts* (1796-7). Hegel's glorification of the state as the embodiment of Absolute Reason is mentioned as a *curiosum* only. No wonder he was popular with the Prussian bureaucracy.

[9] As an example, I mention P. J. A. von Feuerbach's (not to be confused with the philosopher L. A. Feuerbach) criminology: *Kritik des natürlichen Rechts* (1796).

(b) *The Historians' Sociology of Government and Politics.* Writers who were professional historians or at least had an eye for historical reality were bound to do better than utilitarian or other theorists as far as politics is concerned, for it is more difficult for historians to neglect facts that stare them in the face. Edmund Burke, for example, was a man who saw the concrete situation with passionate energy—whether indulging in bursts of wrath or proffering sober advice—and knew how to distill generalizations from them that have established the reputation of his writings as a storehouse of political wisdom even with people who bore no love to his politics: it might be said that he taught politics by the case method and, as everyone knows, very effectively.[13] Again, nobody has ever commended Lord Macaulay for profundity of thought. But as regards insight into the nature of political processes, he was immeasurably superior to James Mill, and his criticism of the latter's presentation of the political theory of utilitarianism in the *Edinburgh Review* (1829) was perfectly adequate as far as it went although it did not go very far. Politics was still a 'science' to him (not the object of a science) though an 'experimental' [14] one—by which he simply meant that the utilitarian principles of politics were out of contact with political reality and that generalizations could be arrived at only by observations of political reality. He did not try to formulate such generalizations explicitly. Had he done so, they would, we may be sure, have turned out to be idealized Whig politics. This was the case also with those historians who did try their hands at political generalization.[15] Finally, let us recall what I believe to be the finest flower of the period's literature of political analysis: de Tocqueville's *De la Démocratie en Amérique* (1835-40).[16] What is the nature of the performance that produced one of the 'great books' of the period? It conveyed no discovery of fact or principle; it did not use any elaborate technique; it did nothing to court the public (especially the American public). An extremely intelligent mind, nurtured on the fruits of an old civilization, took infinite trouble as to observations and brilliantly subdued them to serve an analytic purpose. This was all. But it is much. And I know of no other book that would train us better in the art of succeeding in this particular kind of political analysis.

---

[10] But let the reader keep this in mind: the historical school fought abstract speculation of either the Benthamite 'empiricist' or the German 'idealistic' types, because these were the types with which natural law had become identified; they fought natural law as such. From our standpoint, however, there is no point in doing this, and any generalization produced by jurists of the historical school should also be included in the corpus of natural law, just as the historical economist's generalizations are still economics and may even enter the concept of economic theory (e.g. in the case of 'theories' of the origins of markets).

[11] F. J. Stahl (*Philosophie des Rechts nach geschichtlicher Ansicht*, vol. I, 1830; vol. II, 1837) was a sort of Lutheran Filmer and rose to be a power in the intellectual life of Prussia in the era of Frederick William IV. The title of that work is justified in the case of vol. I by its attack upon utilitarian natural-law rationalism (and, incidentally to this, by sympathy with the standpoint of the historical school of jurisprudence) but is a misnomer for vol. II, where Stahl, having found his bearings, attacked the historical school of jurisprudence and based himself squarely upon Lutheran theology. Informed readers will miss the name of K. Frantz (*Naturlehre des Staates*, 1870), as they will many others, e.g. that of Joseph de Maistre, and the whole contiguous literature on Church and State. In defense, I can only point to the particular purposes of this fragmentary sketch.

[12] It is with reluctance that I leave a topic that was a close neighbor of economics on the continent of Europe and in whose province the explanation may be found of many a peculiarity of continental economics, among other things, of the proficiency of German economists on the institutionalist side of their science: links that had to be fought for elsewhere, especially in the United States at the time of the institutionalist controversy, were a matter of course for the products of many, if not most, continental universities. The continental student of economics absorbed a sociology of legal institutions—that meant much for his intellectual equipment—in many cases before he had had a word of technical economics. I shall therefore mention the names of two eminent men, who were no doubt jurists first and last but who nevertheless helped to form many an economist. Their influence belongs in the next period rather than in the one under discussion, but both published their most characteristic work before 1870. Rudolph von Gneist (1816-95) was a typically Anglophile German liberal, an authority in many fields but especially in constitutional and administrative law. See *Das heutige englische Verfassungs- und Verwaltungsrecht* (1857-63). Rudolph von Jhering (1818-92), *Geist des römischen Rechts* (1852-65). Neither has been translated so far as I know, although later works of both of them were (e.g. Gneist's *Englische Verfassungsgeschichte*, 1882, English trans. 1889; Jhering's *Zweck im Recht*, 1877-83, English trans. 1913).

---

[13] Edmund Burke's (1729-97) name—no particulars are necessary—cannot be omitted from any survey, however sketchy, of the intellectual scenery of the period, though chronologically his most characteristic performances belong to the preceding one. Students of economics should peruse his writings carefully to learn not only how people should reason on political questions but also how people do reason in these matters. As the reader sees, I find it difficult to join the general chorus of admiration for Burke as a thinker. In fact, the man who defined a political party as a group of people who co-operate in order to further the public interest on some principles on which they are all agreed was certainly no profound analyst; moreover, he was clearly infected by the tendency of his time to take rationalizations for analytic explanation. The reader can easily satisfy himself of the lack of realism in Burke's definition by trying to apply it, e.g., to the two great American parties.

[14] It is amusing to observe this use of the term 'experimental.' The utilitarians, being empiricist philosophers and believers in the application of the methods of physics, specifically claimed that *their* procedure was 'experimental.' These attempts by both 'theorists' and 'antitheorists' to appropriate a term that, through the successes of physical experimentation, had acquired a eulogistic connotation also runs through the whole history of economics from the seventeenth century as will be noted again and again. Actually the term as applied to social phenomena is next to meaningless; what the writers who use it mean to convey must be ascertained separately in each case.

[15] The subject being very important for us, I shall mention a few examples: the *Grundzüge der Politik* (1862) by the historian Georg Waitz is by far the most creditable one I know, though not free from intellectualist fallacies; the *Politik auf den Grund und das Maass der gegebenen Zustände zurückgeführt* (1835) by the strongly partisan (liberal) historian F. C. Dahlmann is an able piece of analysis; the *Lehrbuch des Vernunftrechts und der Staatswissenschaften* (1829-35) by the still more partisan (radical) historian K. W. R. von Rotteck is an illustration of the truth that, given sufficiently close-fitting blinkers, a man may completely lose that sense for historical reality which is the main practical advantage to be derived from historical study. Finally, it is convenient to mention in this place a book that belongs chronologically in the next period but is an excellent example of the Political Science of the best historians of the period under discussion: J. R. Seeley's *Introduction to Political Science*

But the period's great performance in the field of political sociology stands in the name of Karl Marx. We are not yet in possession of the facts that are necessary to establish this. They will be supplied in the next section (4b). Here I wish merely to say by way of anticipation that Marx's theories of history, of social classes, and of the state (government) [17] constitute, on the one hand, the first serious attempts to bring the state down from the clouds and, on the other hand, the best criticism, by implication, of the Benthamite construct. Unfortunately, this scientific theory of the state, like so much else in Marxist thought, is all but spoiled by the particularly narrow ideology of its author. What a pity, but at the same time, what a lesson and what a challenge! Two examples will illustrate another type of political analysis that, from negligible beginnings in the eighteenth century, made some advance during that period, though it did not get very far. As soon as political analysis becomes alive to the claims of scientific methods, it is bound to run up against problems of criticism—in the logical, not in the political sense: criticism of political concepts and of political reasoning—and of mechanisms. The book of a man who was himself an eminent politician, Sir George Cornewall Lewis (1802-63) illustrates that

---

(first edited by H. Sidgwick in 1896—the gleanings from Seeley's 'conversation classes' on the subject that were so interesting a deviation from the current practice of formal lectures).

[16] Alexis de Tocqueville (1805-59) needs no introduction, for his name and work have penetrated into secondary schools—a success only the more difficult to explain because it was so thoroughly deserved. Attention is invited to the rest of his writings. See *Oeuvres complètes* (ed. Beaumont, 1860-65).

[17] Marx's truly sociological, i.e. nonspeculative, theory of the state is contained, in a nutshell, in the *Communist Manifesto* and is there summed up in the pithy sentence that a government is a committee for the management of the common interests of the bourgeoisie. There is, therefore, no such thing as a socialist state—the state as such dies in the transition to socialism, a proposition that has been taken over and much emphasized by Lenin(!). It is impossible to say here all that should be said about this theory of the state and of politics. That central sentence is, of course, a half-truth at best. But it suggests indirectly something that is much more important than is that half-truth, viz. the idea that the state (government, politicians, and bureaucrats) is not something to philosophize on or to adore but something to be analyzed as realistically as we analyze, e.g., any industry.

awakening to critical consciousness.[18] The later book of another man who also was something of a politician, though primarily an academic leader, Franz von Holtzendorff (1829-89), illustrates a growing sense of the necessity of analyzing the mechanism of public opinion.[19]

(c) *Environmentalism.* A *Zeitgeist* that contains a component of mechanist—or what amounts almost to the same thing, sensationalist—materialism will, in exact proportion to the relative strength of this component, favor sociological theories that emphasize the explanatory value of environmental factors. Accordingly, we find a streak of environmentalist thought that may be described as a vulgarized form of Montesquieu's.[20] Two examples will suffice. Feuerbach, the philosopher (not the lawyer), made man a product of his physical environment. If we add those qualifications that are necessary in order to raise this proposition to the level at which it becomes possible to discuss it at all, we have here a theory that has, explicitly and implicitly, come to the fore again in our own time. His emphasis, within environmental factors, upon food [21] is also in evidence in our second example, Buckle.[22] If space allowed us to do so, we should have to consider his work under three aspects which, as it is, can only be indicated. First, there is an *idea:* to reduce history to a science by arriving, through 'induction' from observed facts, at 'laws' of the same kind as what Buckle conceived the 'laws' of physics to be. In intention, Buckle's interpretation of history, and not Marx's, is the truly 'materialistic' one—which is, of course, all to the credit of Marx. Nothing is more obvious, however, as soon as one delves into Buckle's work, than the fact that this idea is purely ideological in nature: it is what he wished to carry into effect, whereas he was actually swayed by pure speculation that from first to last forced facts into a preconceived schema. Second, there is the conceptual *implementation* of the idea, consisting of three types of 'laws' that determine social states and their changes—physical, moral (i.e., propositions on human behavior), and intellectual. The latter (mainly growth of technological control over physical environments) supply the motive power of 'progress,' a principle that links up with what we shall presently describe as Condorcet-Comte evolutionism. As far as these aspects are concerned, namely, the analytic ones, even the little we have said about the book is too much: its importance consists wholly in providing a case study in analytic miscarriage, which may teach us to look out for speculative propensities behind a nonspeculative program and for dilettantism behind an apparently large scientific apparatus. But there is, third, the almost unbelievable success this book has had with all types of people, rich and poor, educated and uneducated, English and foreign. It is this success only that raises the book to significance: it was one of the items of the layman's reading, one of the educators of that period's public mind. As such its teaching is an important element in the intellectual scenery we are trying to visualize.

---

[18] *Treatise on the Method of Observation and Reasoning in Politics* (1852)—a forgotten book by a half-forgotten man. Yet both deserve to survive. The former is strongly recommended to the reader because economists greatly need instruction of the kind it imparts. The latter we have had occasion to mention in passing (above, ch. 2).

[19] *Wesen und Wert der öffentlichen Meinung* (1879). Von Holtzendorff also wrote *Principien der Politik* (1869), which does not seem to me to amount to much. None of the other works of this prolific writer (though some of the fruits of his editorial activities) are known to me.

[20] Montesquieu does not seem to me to have overrated the explanatory value of environmental factors. How far environmentalist arguments that occur fairly frequently in the sociological literature of the second half of the eighteenth century—e.g. in Herder's writings—should be traced to his influence, I do not feel able to say. The *Esprit des lois* was one of the most famous and most extensively read books of that century. On the other hand, there were so many other sources from which a man might have drawn environmentalist inspirations that it is difficult to make positive assertions even in cases where Montesquieu was quoted.

[21] L. A. Feuerbach (*Sämmtliche Werke*, 1903-11, vol. x, p. 22) coined the phrase: 'Der Mensch ist was er isst.' The pun loses in translation: 'Man is what he eats'—one of those phrases that express a whole mental world. Feuerbach's writings were part of a literary current that popularized what Marx and Engels so well described as 'vulgar materialism.' Let us notice in passing this very significant fact: many if not all ideas of Feuerbach should have appealed to Marx for they agreed well with one aspect of Marx's work. Nevertheless, Marx fought them in season and out of season (see e.g. *Marx-Engels Archiv*, I, 1926, and Engels' *Ludwig Feuerbach* . . . , 1888; English trans. by A. A. Lewis, 1903), often with arguments that, coming from him, were not very convincing. The explanation is simple, however: whatever else he was, Marx was a highly civilized man; it was beyond him to swallow that sort of thing.

[22] H. T. Buckle, *History of Civilization in England* (2 vols., 1857-61). The work is a torso; in fact it is not more than an introduction to what was conceived as a huge enterprise. There is a considerable Buckle literature.

Like other 'theories,' environmentalism can easily be carried to a point where it becomes obvious nonsense. But within its sphere, it is an indispensable helper of the analyst of social phenomena—as it proved to be, for example, for Michelet. The case may be illustrated by the (in this respect) similar case of 'racialism.' It is a melancholy but very important observation to make that in the social sciences factors are always at work that will drive such theories to the point of nonsense and—what is very much the same thing—turn them into bones of contention for ideological and political parties. Both environmentalism and racialism suit so many books that neither is allowed to make its contribution to our understanding of social processes—their friends and their foes alike join forces to prevent this consummation. Let us notice again a work of the period which, with remarkable freedom from bias, succeeded in balancing the environmentalist and racial element in a way that was quite satisfactory as far as it went: F. T. (*not* Georg) Waitz's *Anthropologie der Naturvölker* (1859-64)—especially the first volume.

4. Evolutionism

Social phenomena constitute a unique process in historic time, and incessant and irreversible change is their most obvious characteristic. If by Evolutionism we mean not more than recognition of this fact, then all reasoning about social phenomena must be either evolutionary in itself or else bear upon evolution. Here, however, evolutionism is to mean more than this. One may recognize the fact without making it the pivot of one's thought and the guiding principle of one's method. The utilitarian system may serve to illustrate this. James Mill would have smiled at a questioner who asked him whether he was aware of the occurrence of social changes, and he would have, in addition, conceived a poor opinion of the questioner's intelligence. Yet his various systems—in economic, political, and psychological theory—were not evolutionary in the sense that his thought in any of those fields *turned* upon evolution. And it is this that shall be the criterion of evolutionism for us, both as regards philosophy—comprising also purely metaphysical speculation—and as regards any 'scientific' field. Evolutionism in this sense asserted itself in the course of the eighteenth century but reached and passed its high-water mark in the nineteenth.

Attention is drawn to the presence of a disturbing factor, the influence of which will be felt in many ways and not only in this section. In itself, the concept of evolution is perfectly free from any valuation except within well-defined standards.[1] As far as this goes, we merely recognize that people will describe a change as progress if they like it, and as retrogression or degeneration if they dislike it. But in the eighteenth century evolution was naïvely identified with progress—toward the rule of *la raison*—that is to say, it carried a value judgment by definition. And this naïve association of ideas persisted throughout the nineteenth century, though signs of its gradual dissolution appeared in serious research work as time went on. The bourgeois whose business and class position prospered had any amount of confidence in 'progress' of certain types, and he and the literary exponent of the bourgeois mind displayed a lamentable tendency to link this confidence in a certain set of desired changes with some ineluctible forces that move civilizations or even the universe. But we must try to keep clear of such infantilisms, however important they are as features of the *Zeitgeist*.

For clarification and illustration, it will be useful to distinguish five different—though often overlapping—types of evolutionist thought, all of which loom large in the intellectual scenery of this period and also in that of the subsequent one: what follows refers to both periods, though instances are taken only from the one under survey.

(a) *Philosophers' Evolutionism.* Hegel is the outstanding example. With every apology for the temerity involved, I shall put the one point that is relevant for the purposes of this book as follows. Let us postulate the existence of a metaphysical entity—no matter what we call it—that *is* ultimate and absolute reality, and let us thus place ourselves on the standpoint of an ultra-idealistic philosophy.[2] Let us, *at the same time and in the same sense*, define the *same* reality as the totality of all actual and potential observational facts. How is this possible? It is possible, if, as, and when we see in these observational facts, as it were, runes that embody (manifestations of) that entity[3]—in much the same way in which we should do so if we adopted straight pantheism in the ordinary sense. Now, that entity is supposed to undergo an immanent evolution in an essentially logical process of theses, antitheses, and syntheses.[4] And so does the observational reality. This is the kind of thing that will always appeal to one type of mind and never to another. We pass on with a definition and a comment. The definition: reasoning from the conception of a metaphysical entity, which in unfolding its own contents produces a sequence of changes in the reality of experience, we call *emanatist*. The comment: the reader will observe that of Hegel's emanatist conception of evolution something remains, even if we drop its metaphysical trappings, namely, the idea or perhaps discovery that reality, as we know it from experience, may be in itself an evolutionary *process*, evolving from inherent necessity, instead of being a set of phenomena that seek a definite state or level, so that an extraneous factor—or at least a distinct factor—is necessary in order to move them to another state or level as the analogy with Newtonian mechanics suggests. This idea, if tenable, is of course extremely important. As regards philosophy, it renders it possible to proceed, for example, from Hegelianism in its original acceptance to what may be termed Hegelian materialism, which many of the so-called Young Hegelians did. As regards sociology, it suggests a novel approach to the facts of social change.

---

[1] Thus, within the range of the accepted standards of the dental profession, it is a meaningful proposition to aver that at the present time teeth are being extracted 'more efficiently' than a century ago and even that dentist A extracts teeth 'more efficiently' than does dentist B. An analogous statement applies to technical economic theory. But obviously this is no longer so when it comes to comparisons of social structures or civilizations and outside of the range of specified standards in general.

[2] Idealism as applied to German philosophy from Kant to Hegel has, of course, nothing whatever to do with idealism in the ethical sense.

Before going on, we may notice two other methods by which philosophers sometimes contrived to impart to their philosophies an evolutionary slant. 'Progress' was in the air and, like other people, philosophers enjoy being up to date. The agnostic or materialist, especially of the semi-popular variety, was apt to substitute intellectual progress for the entities that he discarded, that is to say, he was apt to raise a loan from what will be described below (d) as Condorcet-Comte evolutionism; or else he was apt to exploit biological evolutionism (c) for philosophical purposes. Whatever we may think of this as a philosophy, it made popular literature.

---

[3] This is what Hegel's famous phrase was meant to convey (if we equate our metaphysical entity to reason): whatever is, is rational (conforms to reason) and whatever is rational (thinkable), is. As meant, this does not lend any support to conservative attitudes. But the reader will have no difficulty in realizing how easily it can be made to do so. Moreover, Hegel's phrasing invites such an interpretation. This was even an important factor in his success.

[4] The irreverent did not fail to notice that here was an opportunity of proving Hegel's system to be nonsense. Misguided by their inability to rise to Hegelian heights, they pointed—with a vicious smile—to the fact that this piece of philosophizing cannot be readily translated into English. The German verb *aufheben* means both to cancel and to raise. Hegel averred that a thesis, *A* is *B*, and its antithesis, *A* is not *B*, *aufheben* each other into something higher, a synthesis that comprises the content of both. But contradictory statements do not *aufheben* each other in the sense of *raising* each other into something more comprehensive: they simply *cancel*, i.e. annihilate, each other—which would be rather serious for Hegel and evolution. It is, of course, possible to save the situation. A warning to us remains, however.

(b) *Marxist Evolutionism.* I have just adverted to the possible implications for sociology that a despiritualized Hegelian philosophy might harbor. This suggests that here we have after all more than a phraseological influence[5] of Hegel upon Marx. If, nevertheless, we maintain substantive autonomy of Marx's so-called Materialistic Interpretation of History as against Hegelism, and if we list it as a separate type of evolutionism, we allow ourselves to be guided by two considerations. First, Marx's theory of history developed independently of Marx's Hegelian affiliation. We know[6] that his analysis started from a criticism of the current (and apparently immortal) error that the behavior that produces history is determined by ideas (or the 'progress of the human mind'), and that these in turn are infused into actors by purely intellectual processes. To start with this criticism is a perfectly sound and very positive method but has nothing to do with Hegelian speculation. Second, Marx's theory of history is a working hypothesis *by nature.* It is compatible with any philosophy or creed and should therefore not be linked up with any particular one—neither Hegelianism nor materialism is necessary or sufficient for it.[7] What remains is, again, Marx's preference for Hegelian phrasing—and his own and most, though not all, Marxists' preference for anything that sounds anti-religious.

---

[5] An example of the purely phraseological influences, of which there are many, will be noticed in passing. The untutored reader of Marx's writings may wonder why Marx speaks so often of 'contradictions' of capitalism when he means nothing but mutually counteracting facts or tendencies: these *are* contradictions from the standpoint of Hegelian logic. This has had an amusing consequence. To this day, the average Marxist, accepting the word Contradiction in the sense it carries in ordinary logic and parlance, infers that Marx wished to charge the capitalist system with *logical* incompatibilities in this ordinary sense every time he spoke of 'contradictions'—which, of course, is not the case.

[6] See e.g. Marx's introduction to his *Contribution to the Critique of Political Economy* (publ. by Kerr, Chicago, 1904). The original German edition (*Zur Kritik der politischen Oekonomie*) was published in 1859, the *Einleitung* (introduction) in the *Neue Zeit*, 1902-3; the English translation by N. I. Stone includes the 'recently published' introduction in an appendix.

[7] I have found that this statement is likely to cause surprise. But proof is easy. For we may fully accept the doctrine of freedom of individual will in the sense in which it is taught, e.g., by St. Thomas Aquinas, and still go on to argue that the exercise of this free will, being limited by physical and social data, will in general produce a course of events in conformity with these data. The economic interpretation is nothing but a hypothesis about what, in turn, determines these data, and per se implies neither absence of the individual's moral responsibility for his acts nor refusal to admit the possibility of supermundane influence upon these data themselves and the ways in which they work out. Marxists, it is true, will not admit this. But they will not admit this for reasons—beliefs, philosophies—that are extraneous to the logically essential content of the economic interpretation of history: *philosophical* determinism is, as a matter of fact, mostly associated with sponsorship of the latter, but in logic it has nothing to do with the *methodological* determinism that is implied in it.

Both the achievement embodied in that hypothesis and the limitations of this achievement may be best conveyed by means of a brief and bald statement of the essential points. (1) All the cultural manifestations of 'civil society' —to use the eighteenth-century term—are ultimately functions of its class structure.[8] (2) A society's class structure is, ultimately and chiefly, governed by the structure of production (*Produktionsverhältnisse*), that is, a man's or a group's position in the social class structure is determined chiefly by his or its position in the productive process. (3) The social process of production displays an immanent evolution (tendency to change its own economic, hence also social, data). To this we add the essential points of Marx's theory of social classes, which is logically separable from points (1) to (3) that define the economic interpretations of history but forms part of it within the Marxian scheme. (1') The class structure of capitalist society may be reduced to two classes: the bourgeois class that owns, and the proletarian class that does not own, the physical means of production, which are 'capital' if owned by employers but would not be 'capital' if owned by the workers who use them. (2') By virtue of the position of these classes in the productive process, their interests are necessarily antagonistic. (3') The resulting class struggle or class war (*Klassenkampf*) provides the mechanisms—economic and political—that implement the economic evolution's tendency to change (revolutionize) every social organization and all the forms of a society's civilization that exist at any time. All this we may sum up in three slogans: politics, policies, art, science, religious and other beliefs or creations, are all superstructures (*Überbau*) of the economic structure of society;[9] historical evolution is propelled by economic evolution; history is the history of class struggles.[10]

This is as fair a presentation of Marx's social evolutionism as I am able to provide in a nutshell. The achievement is of first-rank importance[11] although the elements that enter into it are of very unequal value or, rather, unequally impaired by obvious ideological bias. Least valuable for any but agitatorial purposes is the theory of social classes that Marx associated with his economic interpretation of history: the two-class schema is all but useless for serious analysis; exclusive emphasis upon class antagonism is as patently wrong—and as patently ideological—as is exclusive emphasis upon class harmony of the Carey-Bastiat type (see below, ch. 4); and the proposition that the evolution of forms of social organization is brought about by a mechanism that can be described exclusively in terms of the struggle between those two classes is a simplification that eliminates the essentials of the mechanisms actually at work. A qualification must, however, be added: if we get from Marx an ideologically warped definition of classes and of class antagonisms, and if in consequence we get an unsatisfactory description of political mechanisms, we nevertheless get something very worth having, namely, a perfectly adequate idea of the importance of the class phenomenon. If in this field there existed anything like unbiased research, Marx's suggestions would have led long ago to a satisfactory theory of it.

---

[8] I repeat that the term 'function' here used does not imply causal determination. In fact, an attempt to insist on such 'absolute' or 'mechanical' determination would not achieve anything except to make the theory very easy to refute. Both Engels and Plekhanov, the chief Marxist authorities on the subject, have seen this and both relaxed considerably on the stringency. Emphasis upon 'ultimately' was one of the means of doing so.

[9] One aspect or application of this theory we have discussed in Part 1, viz. the doctrine of the inevitable 'ideological bias' of all thought.

[10] Marx's ideas on social evolution and classes are, of course, basic for everything he ever wrote, and comments on them are strewn all through his works—which does not make it any easier to do justice to them. But of all his publications, the following seem to me the most important sources to be used in any attempt at interpretation: the *Communist Manifesto*; the *Class Struggles in France*; the *Eighteenth Brumaire of Louis Bonaparte*, and the *Critique of Political Economy*. (All available in English translations; for details as to dates and publishers, see Sweezy, op. cit. p. 382.)

[11] This achievement should, I believe, be attributed to Marx alone. For every performance of such scope it is, of course, possible to name forerunners. But there were rather less of them than we are accustomed to find in comparable cases. The only

But the economic interpretation of history is a different matter. If we reduce it to the role of a working hypothesis and if we carefully formulate it, discarding all philosophical ambitions that are suggested by the phrases Historical Materialism or Historical Determinism, we behold a powerful analytic achievement. Points (1) and (3) may then be defended against objections, most of which turn out to rest upon misunderstandings.[12] Point (2) is less reliable: it

---

claimant for whom it is possible to argue at all is Lorenz von Stein (1815-90), whose *Socialismus und Communismus des heutigen Frankreichs* (1842, later ed., entitled *Geschichte der socialen Bewegung in Frankreich*, 1850, newly edited, 1921) is in fact an important piece of analysis that links up the development of socialist ideas with the realities of social movements and economic changes. This, however, is not the economic interpretation of history; still less is it possible to find the latter in the socialist writers themselves, whom Stein discussed, or in the French historians of the revolution, the restoration, and the Orléans regime. So far as my knowledge of them entitles me to judge, they all emphasize more or less the economic element in the historical processes they describe which they could hardly have helped doing. But obviously this is not enough. I suspect that those who find in this literature anything suggestive of the economic interpretation of the historical process as a whole entertain a different conception of the latter than I thought it proper to adopt. Mere recognition of the importance of the economic factor is a triviality and neither distinctive nor meritorious in itself. The case of Saint-Simon, which may be an exception, will be stated below.

[12] By simple experiment, the reader may easily satisfy himself how well point (1) works. Take e.g. so modest a 'cultural manifestation' as the modern murder story. Observe its chief characteristics—not forgetting its English—and correlate them with the salient facts about the social structure of our time. You will not fail to enjoy an enlightening experience.

I take this opportunity to advert to one of those misunderstandings of which, on one occasion, Engels himself was guilty. Taking 'materialism' mistakenly in its ethical sense, some writers have taken what they called 'historical materialism' to mean that men are actuated by material, i.e. economic, interests as motives in the psychological sense. Marx's theory does not mean this and has room for all kinds of motives.

works well with some historical patterns and not at all with others.[13] This problem Marx does not seem to have taken very seriously. But there was another, to the solution of which he devoted the bulk of his giant powers for the rest of his life. Obviously, the vast fabric, of which the economic interpretation of history was the base, would have had to remain incomplete without a full analysis of that immanent evolution of the economic sector on which the evolution of human civilization as a whole was made to rest. For him the economic interpretation of history was, therefore, still more a program than it was an achievement to be valued for itself.

We have reached a point of vital importance for a proper understanding of Marx's work. On the one hand, we can now visualize his unitary Social Science, the only significant all-comprehensive system that dates from this side of utilitarianism: we see the manner and the sense in which he welded into a single homogeneous whole all branches of sociology *and* economics—a venture that might well dazzle the modern disciple even more than it dazzled Engels, who stood too near the workshop. On the other hand, we now see Marxist economics in its true light. Its individual features, or some of them, will come in for notice and appraisal in their places. Here I wish only to insist on the greatness of the conception and on the fact that Marxist analysis is the only genuinely evolutionary economic theory that the period produced.[14] Neither its assumptions nor its techniques are above serious objections—though, partly, because it has been left unfinished. But the grand vision of an immanent evolution of the economic process—that, working somehow through accumulation, somehow destroys the economy as well as the society of competitive capitalism and somehow produces an untenable social situation that will somehow give birth to another type of social organization—remains after the most vigorous criticism has done its worst. It is this fact, and this fact alone, that constitutes Marx's claim to greatness as an economic analyst. That he was more than an *economic* analyst we have seen in this section. That he was more than an *analyst* need not be explained again.

---

[13] The Marxist principle can be illustrated by such processes as the elimination of the artisan class by large-scale manufacturing industry. But as Dühring pointed out, other instances can be adduced to show that this 'causality' is often reversed—the truth being of course that there is interdependence between the conditions of production and the social structure. The situation of the Marxist principle can be somewhat improved by recognizing the fact that social structures may outlive the conditions of production that created them—which will account for a certain number of discrepancies without destroying the theory. Another device is more dangerous: we might define, e.g., the activity of a tribe of warlike conquerors as 'productive' and then say that the social organization that results in conquered countries still comes within the range of the Marxist interpretation. But this is very near to making a tautology of it.

[14] We deal elsewhere with the Smith-Ricardo-Millian contribution to the theory of economic change. Even those readers who see merit in it, granting even the possibility that it may have given Marx a basis from which to start, will have to admit that it looks embryonic beside his.

[For a discussion of the views of Marx and Schumpeter on the topics covered in this section, see O. H. Taylor, 'Schumpeter and Marx: Imperialism and Social Classes in the Schumpeterian System,' *Quarterly Journal of Economics*, November 1951. This is a review article of Schumpeter's *Imperialism and Social Classes* (English trans., ed. with an introduction by Paul M. Sweezy, 1951).]

(c) *Historians' Evolutionism.* Mere preoccupation with the problems of describing the events of an ever-changing world does not spell evolutionism in the sense of this section. Professional historians, therefore, are not evolutionists by profession. They become evolutionists—of a distinct type—only when they try to arrange states of society—economic, political, cultural, or general ones—into sequences that are supposed to be necessary in the sense that each such state is the necessary and sufficient condition for the emergence of the one that follows it. The oldest and most primitive way of doing this is by constructing typical stages through which an economy must pass. This method was represented in that period by Friedrich List, whose scheme—hunting, agriculture, agriculture plus manufacture, agriculture and manufacture plus commerce—met with deserved criticism from Karl Knies:[15] we should indeed have put down this scheme as completely worthless were it not for the fact that it may be used (and was used by List) as a simple expository device for impressing upon beginners (or the public) the lesson that economic policy has to do with changing economic structures and therefore cannot consist of a set of unchanging recipes. Another example is Bruno Hildebrand's scheme: exchange economy, money economy, credit economy. Beyond this there is not much to report in this category—the better a historian, the more averse he is to such constructions—except that a vague belief in evolutionary sequences, such as historical sequences that were supposed to bear analogy with the youth, manhood, and old age of individuals, are not infrequently met with in historical writings of that period. An economist and economic historian who indulged in this belief without however being misled by it, as far as I can see, was W. Roscher.[16] It is worth noting that this belief in 'laws of economic history' constitutes one of the main differences between his methodology and Schmoller's, who nevertheless had a type-series of his own: village economy, town economy, territorial economy, and national economy.

(d) *The Intellectualist Evolutionism of Condorcet and Comte.* Condorcet,[17] more than any other writer, elaborated the theory of social evolution that is specifically associated with the thought of the Enlightenment and is present, implicitly or explicitly, in the writings of all the votaries of *la raison:* let us call it Intellectualist Evolutionism. It is the last word in simplicity. Reduced to its essential content, it comes to this: human reason, a given force, wages an incessant war of conquest on man's physical environment and, at any given stage, on the beliefs or habits of thought that mankind has acquired at previous stages of its history. From this incessant struggle results, on the one hand, an indefinitely increasing insight into the true laws of nature and, in consequence, an even more perfect technological control over the forces of nature and, on the other hand, an indefinitely increasing freedom from erroneous and antisocial beliefs and propensities: human intellect, perfecting itself, perfects the whole of human nature, hence also human institutions, without assignable limit. Since many readers' minds are presumably imbued with this theory—perhaps to the point of accepting this 'progress of the human mind' as a matter of course—we had better make sure that we understand the objection to it: it fails because it postulates what it is to explain. Changes—adaptive and, possibly, also autonomous—in beliefs, in stocks of knowledge and techniques, and in habits of thought are no doubt historically associated with other manifestations of social evolution. But they are conditioned, to say the least, by the facts of a changing social structure, and so are their *modi operandi*. If we attribute, say, modern positivism or the modern airplane to the progress of the human mind, we have evidently not done much toward their explanation. In fact, we have done nothing: we have only renamed the problem. If, in order to remedy this, we appeal to the perfectibility of the human mind, we have still done nothing: we have only postulated the solution. And if, recognizing this, we introduce additional factors of explanation, for example, biological ones, we have left the moorings of intellectualist evolutionism.

---

[15] See his *Politische Ökonomie vom Standpunkte der geschichtlichen Methode* (1853, enlarged ed., 1883).

[16] The work of List, Hildebrand, and Roscher will be discussed below in ch. 4, sec. 5.

[17] Marquis de Condorcet (1743-94), *Esquisse d'un tableau historique des progrès de l'esprit humain* (1795; see above, Part II, ch. 2, sec. 7d).

But in spite of its patent inadequacy, this theory survived in the liberal or progressive circles that continued the tradition of the Enlightenment. Lecky and Buckle, however much their arguments may differ, can be mentioned again in illustration of this. For us, however, Comte's position is of particular interest. His schema or 'law' of three stages, according to which civilization evolves from a religious or magical stage to a metaphysical and then to a scientific one, clearly hails from the thought of the Enlightenment: it does not differ essentially from Condorcet's. Moreover, it is not only unbelievably narrow but also, in Comte's own sense, speculative and unscientific: research on the lines of his 'positive' program would have immediately revealed the presence of factors and mechanisms that cannot be reduced to the one factor embodied in that 'law.' Observe, however, that, superficially, the law seems easy to verify: rational scientific procedure (though not in politics) is in fact one of the features that are characteristic of our own time; and magic is in fact characteristic of the primitive mind—the question is only how much this means and how far the correlation admits of causal interpretation.

There is one more point to be noticed. The religious, metaphysical, and scientific attitudes are evidently social and not simply individual phenomena. Therefore, Comte's stages may be said to be stages in the development of a collective or group mind. Much more definitely than Condorcet, Comte in fact adopted this concept and he did something toward elaborating it. There is, of course, a world of difference between his collective mind and the national soul of the romanticists. Viewed as tools of analysis, however, both come to much the same thing and both have influenced the work of later sociologists and social psychologists.

(e) *Darwinian Evolutionism.* This is the only kind of biological evolutionism to be noticed here. Lamarck's influence was largely, though not wholly, superseded by Darwin's (who, however, was generous in his references to Lamarck); and Mendel, though he published his three laws in 1866, did not exert any direct influence at all.[18] The 'Historical Sketch' added by Darwin to the third and later editions of the *Origin of Species* will tell the reader the fascinating story of the gradual emergence of the decisive ideas, so that nothing needs to be said about it here.[19] It is, however, necessary to offer the following comments on the social significance of the book and on its significance for the social sciences.[20]

---

[18] G. J. Mendel (1822-84), an Augustinian monk, not only did excellent experimental work—this is professional opinion; I have, of course, none of my own—but also offered the theoretical interpretation of it that proved acceptable to biologists when his results were independently rediscovered (about 1900). He refrained from any application to social processes. Since we are interested in the sociology of science, the question arises: what can we learn from this case of neglect of a most important performance? Examination of the case seems to show, however, that it teaches us nothing. Robert Mayer personally communicated his discovery (mechanical equivalent of heat) to men (one man at least) of indubitable professional standing, who could and should have understood and promulgated it. Cournot published his *Recherches* (see below, Part IV, ch. 7) in the broad daylight of one of the great intellectual centers. But Mendel lived in a convent, situated in a provincial town, and published his results in an obscure local periodical, that is, in a manner that amounted to hiding them. Thus, this case of neglect is self-explanatory.

[19] The reader is urgently advised to peruse it carefully. It is one of the most important pieces of scientific history ever written, and presents a case study about one of the objects of our interest—the ways of the human mind and the mechanisms of scientific advance. In addition, it elucidates a concept that plays some role in our own story, the concept of Inadequate Acknowledgment of Priorities. Darwin illustrates the meaning of this concept by presenting an ideal instance of what is Adequate Acknowledgment. In everything he did, that man was a living and walking compliment to himself and also to the economic and cultural system that produced him—a point recommended to the reader whenever he feels like ruminating on the civilization of capitalism (and, incidentally, about more modern forms of organization of research).

Charles Darwin (1809-82) took long in evolving, still longer in publishing, the fruits of his labor. *The Origin of Species . . .* was published in 1859. *The Descent of Man and Selection in Relation to Sex* was published in 1871, after Vogt and Haeckel (also others) had already pronounced in favor of its main theses. Chapters 3, 4, 5, and 19 treat matters directly relevant to general and economic sociology.

Herbert Spencer's essay, which Darwin commends so generously, appeared first in the *Leader*, 1852, and his *Psychology* in 1855, whereas Mill's *Principles*, the restatement of 'classic' economic thought, appeared in 1848.

[20] The reader will observe that in what follows I do not of course presume to judge the book as a professional performance in its own field. The delicate question of a research worker's proper behavior in matters that involve the results and procedures in fields other than his own, therefore, does not arise at the moment, though it does arise in connection with 'Darwinist' social theories.

In the first place, the *Origin of Species* and the *Descent of Man* make one of the biggest patches of color in our picture of that period's *Zeitgeist*. Their secular importance for mankind's cosmic conceptions is comparable with that of the heliocentric system. They were very widely read by the general public, passionately discussed, and effective in refurnishing the bourgeoisie's mental house, though it seems that, in most cases, this new furniture did not oust metaphysical furniture that still existed but only occupied empty space. Our fundamental beliefs and attitudes are beyond the power of any book to make or shake; in particular, I do not think that any cultivated person will find his faith destroyed through reading Darwin, provided that person has any faith to destroy.[21]

In the second place, however much or little we may think of the causal role of Darwinism, its symptomatic importance is beyond question. It came, and rode to success, exactly when it should have done so according to the Marxist theory of intellectual superstructures. And it was one current only in a broader river as the independent but analogous developments in geology suffice to show.[22] This was the same river that also carried along the other evolutionisms that we have been discussing above. But in all other respects these were logically independent of either Darwinism or any other biological theory: it is quite important to realize this in order to avoid confusions that threaten our understanding of the intellectual history of the period. Marx may have experienced satisfaction at the emergence of Darwinist evolutionism. But his own had nothing whatever to do with it, and neither lends any support to the other.

In the third place, Darwinism or Darwinist talk did intrude into sociology and economics later on. This will be touched upon in our survey of the intellectual scenery of the next period (Part IV, ch. 3). For the period under discussion, I can find no significant influence upon the social sciences apart from what we may conceive Darwinist influence to have done to people's general habits of thought.[23] Both Darwin and Spencer contributed to psychology, and the latter displayed a propensity for sociological applications from the first. But this is all. In concluding, I wish to comment on Darwin's remark to the effect that he derived inspiration from Malthus' theory of population. It seems very hazardous, to be sure, to dissent from a man's statement about his own mental processes. But quite insignificant events or suggestions may release a given current of thought; Darwin himself did not include Malthus' work in the Historical Sketch mentioned above, though he did refer to it in his introduction; and the mere statement that 'more individuals of each species are born than can possibly survive' (which, moreover, is doubtful Malthusianism) is, in itself, not more than a platitude. I am afraid, therefore, that the service rendered by economics to the evolution of the Darwinian doctrine bears some analogy to the service rendered to Rome by the celebrated geese.

---

[21] I say *cultivated* person because the case is different for the untrained mind that lacks resources for interpretative and critical defense. But, then, the untrained mind takes shelter behind authority.

[22] These are associated with the name of Sir Charles Lyell (1797-1875) *almost* as much as biological evolution is associated with the name of Darwin. His *Principles of Geology* (1830-33) does not quite 'let the murder out' but, by implication, it says as much as does his *Geological Evidences of the Antiquity of Man* (1863).

[23] In 1872, Walter Bagehot published his *Physics and Politics* (more appropriate titles would have been *Biology and Sociology* or *Biological Interpretation of History*), which uses, among other things, Darwinian social psychology. In itself no more than a piece of brilliant dilettantism, the book contains many suggestions that came to fruition later on. It is still worth reading.

5. Psychology and Logic

The most interesting products of that period's work in the field of psychology are those that anticipate, or at least herald, the developments of the subsequent period. I am referring to the cerebral anatomy of P. J. Cabanis, F. J. Gall (whose work also includes the first theory of reflex action), Sir Charles Bell, and P. P. Broca; to the physiological or experimental psychology of Tetens and Bonnet, later on continued with much greater success by Johannes P. Müller, E. H. Weber, R. H. Lotze, G. T. Fechner; to the related line taken by Claude Bernard;[1] and, if we insist on including *Völkerpsychologie* in psychology at all, to the work of F. T. Waitz, who was mentioned above in the section concerned with Environmentalism. Furthermore, if we also include philosophies about the collective mind—and if we choose to call them the harbingers of modern social psychology—we have to add, on the one hand, Comte and, on the other hand, Herder and many other 'romantics.'

[(a) *Associationist and Evolutionist Psychology.*] But more directly relevant for the possibility of a psychological foundation of technical economics—if indeed we have any use for such a foundation—are the psychologies of Herbart (1776-1841) and Beneke (1798-1854).[2] The former worked out a simple conceptual apparatus for the analysis of psychic phenomena as they are given by introspective observation without recourse to physiology. Economists might have learned something from him, though more from his methods than from his results. Barring a few quotations that do not mean anything, I have not however been able to find any instances to prove that either his psychology or his general philosophy exerted any influence upon the professional work of economists. I wonder whether the same should be averred for the element in that period's psychological work that is by far the most *important* one from the standpoint of a history of economics—Hartleyan associationism. This associationism should have been obsolete by then but was revived by a new edition of Hartley's work (1791) and re-expounded with brilliant efficiency by our own colleague James Mill:[3] the mind, a Lockian blank; psychic life, a mechanical system of associations. Even J. S. Mill felt unable to rest content with this, and A. Bain was to combine it with Darwinian elements and elements derived from the German physiological psychologists into something that was pretty far removed from associationist orthodoxy. But for us the question arises: since this associationist orthodoxy was part of Benthamite orthodoxy, shall we not expect that it influenced the economics of the group that was another part of it? Of course, we shall—but we shall be disappointed. The case illustrates very well the nature of the relation of a comprehensive system to its parts. Psychological associationism agrees all right with the utilitarian philosophy or the utilitarian theory of ethics or of behavior in general and in this sense does implement the rest. But if, on the strength of this, we proceed to examine James Mill's little treatise on economic theory, we find that its propositions are completely independent of associationist psychology and are just as compatible with any other: though a province of the Benthamite empire, the economics of the utilitarians was a self-governing province that could have lived equally well if severed from the empire. This verifies a result already arrived at in other connections.[4]

---

[1] These names are mentioned merely as pointers for readers who, if they should wish to go further, will meet them in any history of psychology—which is why I refrain from giving titles and dates. The names of Cabanis, Broca, Weber, and Fechner are associated with performances of particular interest to us. Some will be mentioned again in the corresponding chapter and section of Part IV so that we do not lose our thread. The reader will understand, of course, that I am not competent to judge the value of such work as Gall's or Lotze's in its technical aspects and that in consequence my choice of names may be misleading: the list is the list of an economist whose impressions are in part due to chance reading (guided, however, to some extent, by professional advice) and chance contacts. The name of Broca, e.g., stands where it does because this author combined to an unusual degree research in brain anatomy and in cultural anthropology, but also because his work impressed me greatly in my formative years.

[2] See e.g. J. F. Herbart's *Lehrbuch zur Psychologie* (1816) and his *Psychologie als Wissenschaft. . .* (1824-5). Herbart's very influential philosophy and pedagogics do not interest us here. F. E. Beneke's *Grundlegung zur Physik der Sitten* (1822; the opposite pole to Kant's *Grundlegung zur Metaphysik der Sitten*) and *Lehrbuch der Psychologie als Naturwissenschaft* (1833) make psychology the only basis of logic, ethics, and aesthetics and afford an excellent illustration for what is meant in the present book by Psychologism.

The only thing that needs to be added is evolutionist psychology. As has been mentioned, both Darwin and Spencer faced the problem of the manner in which the human mind acquired each 'mental power': they attempted to construct genetic theories of 'instincts,' emotions, curiosity, memory, attention, beliefs, moral sense, social virtues, and the like. It should be observed that such endeavors are not psychology in the ordinary sense: for example, analysis of the faculty of 'memory' is one thing, and a hypothesis on how we came to have this faculty is another thing. However, genesis may suggest truly psychological theories, and it is understandable that Darwinian influence began to assert itself in professional psychology before long. Economists, however, did not take to this line of research, though it has obvious bearings upon problems of economic behavior and of its malleability, say, in a socialist organization of society—something worth pondering!

---

[3] *Analysis of the Phenomena of the Human Mind* (1829).

[4] Observe, in particular, that the same thing also holds for Hume: his economics has nothing whatever to do with either his psychology or his philosophy. And so for Locke. On the other hand, the relation of associationism to utilitarian economics is complicated by the fact that Bentham's own economics differed from the economics of the other utilitarians who were his followers in everything else.

[(b) *Logic, Epistemology, and Cognate Fields.*] In these fields[5] substantial advance would have to be reported both as to philosophical foundations (Kant; Hegel's *Logic* is not logic in any technical sense though relevant to it in several points) and as to formal and practical developments (Lotze, De Morgan). From our standpoint, it is important to mention the work of a man who holds a key position in the history of the fields within our range of vision, Richard Whately[6] (Anglican archbishop of Dublin). And of great significance for the picture of that period's *Zeitgeist* is the effort made by another key man to realize a desideratum that has been formulated again and again—in our own day, by J. Dewey—to bring logic nearer to the actual procedures of science: Whewell's *History of the Inductive Sciences* (1837).[7] The program of *modern* empiricist logic—as taught by the Vienna positivists such as Carnap, Frank, Richard von Mises, Schlick—is to analyze scientific procedure and to do away with, as not only irrelevant but meaningless, everything else, especially all 'metaphysics.' Whewell was, of course, far removed, subjectively, from either this program or the conceptual constructs with which it is being implemented. But, objectively speaking, his book, owing to the influence it exerted on Mill's *Logic*, is a landmark on the long road that leads toward logical positivism.

---

[5] If we may call mathematics a cognate field, it was the one that made the biggest strides. About these nothing can be said here except that this period—following as it did upon the 'heroic age of mathematics' in which the excitement of pioneer discovery had all but crushed the interest in logical foundations and in critical analysis of concepts and methods—laid the groundwork of modern (rigorous) mathematical reasoning. But a few data on probability must be mentioned, owing to the importance of the subject for statistics and for economic theory. Laplace's *Théorie analytique des probabilités* was first published in 1812; his *Essai philosophique* (which is quite eighteenth century, however) in 1814; Poisson's famous *Recherches* in 1837; Cournot's *Exposition de la théorie des chances et des probabilités* in 1843; P. L. de Tchebycheff's paper ('Des Valeurs moyennes' in Liouville's *Journal de mathématique, pure et appliquée*), 1867; Venn's *Logic of Chance* (often invoked by Edgeworth) in 1866. Fechner's *Kollektivmasslehre* (1897) belongs in this period though not chronologically. The same applies to J. von Kries's *Principien der Wahrscheinlichkeitsrechnung* (1886). The Cournot of probability is the great economic theorist (see below, Part IV, ch. 7, sec. 2). My high opinion of his theory of random events is a layman's opinion. But it was shared by the late Professor Czuber of Vienna.

[6] *Elements of Logic*, which appeared originally as an article in the *Encyclopaedia Metropolitana* (1826). For his work in economics, see ch. 4 below.

[7] William Whewell's (1794-1866) powerful and masterful personality belongs to, and illustrates at its best, that class of scientific men whom we have called Academic Leaders: he was a peerless influence in Trinity College and in Cambridge generally, one of those environment-creating individuals who belong in the history of science even if they never wrote a line. Such was not Whewell's case, however. The *History* is not only a work of erudition but a live source of inspiration (so it was to J. S. Mill), though his *Philosophy of the Inductive Sciences* (1840) is disappointing (at least, so it is to me) and though his *Elements of Morality including Polity* (1845) has been deservedly forgotten. He was also something of an economist. His *Lectures* (1852 and 1862) do not, it is true, amount to much, though he was far too able ever to be quite uninteresting. But he displayed sense for quality by editing the works of Richard Jones (see below, chs. 5, 6) and a touch of originality by making an attempt that no commonplace mind would have made in his day, viz. to express mathematically a few propositions of the economic theory of his time (3rd vol. of the *Cambridge Philosophical Transactions*). This effort does not go beyond stating in symbols what had already been stated in

[(c) *J. S. Mill's* Logic.] These scanty remarks have prepared us for a discussion of the work in which we are primarily interested. From our standpoint, J. S. Mill's *Logic* must hold a place of honor, not only because we claim the author for our own, not only because we economists are much more likely to turn to it than to any other methodological treatise of that time, but also because it was one of the great books of the century, representative of one of the leading components of its *Zeitgeist*, influential with the general reading public as no other Logic has ever been. A less striking patch of color in our picture than is the *Origin of Species*, it is hardly a less indispensable one—although it does not stand out, as does the *Origin of Species*, when we look back on the historical sequence of performances and ideas that produced the situation of today in the respective fields, and although Mill's [8] book is dead in a sense in which Darwin's is not.

> The best way of explaining, to economists, the nature of Mill's performance is to point out the family likeness that exists between his *Logic* and his *Principles of Political Economy*, which will be fully discussed in the appropriate place below (ch. 5). With admirable modesty, Mill disclaimed, in both cases, any pretense 'of giving the world a new theory of intellectual operations' or of economic processes (see the prefaces to the first editions of both books). In both cases, his aim was

---

words and therefore does not really constitute mathematical economics (there is no mathematical *reasoning*). But his rudimentary demand analysis, considering its date, does not quite deserve Jevons' contemptuous verdict that has since been repeated many times. All this is mentioned here because the brevity of our sketch will not permit notice of performances such as Whewell's in their appropriate places.

[8] J. S. Mill, *A System of Logic, Ratiocinative and Inductive, being a Connected View of the Principles of Evidence and the Methods of Scientific Investigation* (1843). One has in mind the success of this book, as much as or more than the success of its author's *Political Economy*, when one speaks of Mill's sway over the generation of English intellectuals that entered upon their careers in the 1850's and 1860's. Abroad, part of the reading public was impervious to such influence. But the rest embraced Mill's message with even greater enthusiasm. The book was found in the house of a peasant in Ireland. It was called the 'book of books' by an accomplished Viennese woman (a Fabian and suffragist) who felt herself to be progress incarnate. It occupied a place of honor not much below Plato's in the mind of at least one *philological* philosopher I knew as a boy—all of which I say in order to convey, first, that the book was a living force in bourgeois civilization and, second, that the correlation between individuals' enthusiasm for it and their competence to judge it was not quite satisfactory.

to co-ordinate existing elements of knowledge, to develop them, and, as he liked to put it, 'to untie knots' (*scilicet* in *existing* strings). In neither case did he succeed completely; but in both he did eminently useful work, work that was perhaps all the more pregnant with suggestions because it contained stimulating discrepancies of doctrine.

Both works, besides being of the same class of performance, reveal in a similar manner the mental stature and the—shall I say 'moral'?—propensities of their author. Within the range of his comprehension, he was eminently fair and fully resolved to open the doors of his mind to ideas of widely different origin—in the *Logic* he went so far as to pay (via a quotation from Condorcet) a well-deserved compliment to scholastic performance. He was 'matter of fact': though his mind was not 'practical' in every sense of the word, he was always 'practical' and even pragmatist in intention, the practically useful result attracting him before everything else. In the case of the *Logic*, his practical purpose was to analyze scientific procedures with a view, first, to establishing their validity ('to appraise evidence') and, second, to developing rules that might inspire or guide research. This makes it very difficult to describe his fundamental standpoint or standpoints in terms of *modern* 'empiricist' and 'positivist' logic, for the problems and methods that are characteristic of the latter and divide its staff of workers (especially in the *Grundlagenforschung* of mathematics) were largely beyond his ranges of vision and interest. (Wherefore it is unjust, by the way, to criticize from a modern standpoint occasional utterances of his that *seem* to be relevant to modern controversies.) But this essentially practical purpose of the *Logic* also renders it difficult to describe Mill's fundamental views in terms of *older* philosophies. The significance of the Kantian revolution he hardly grasped. In a general way, it may be said that his philosophy had its roots in the English empiricism of the Locke-Hume tradition and, in particular, that it had an associationist psychological background. But I believe, though I cannot prove here, that neither statement is entirely correct. In any case, Mill was not narrowly empiricist or narrowly associationist: Hartleyan associationism comes in for criticism in the *Logic*, especially at a strategic point in Book VI.

The purpose of the book almost makes it a complement of Whewell's, to which in fact it owes much. Let us put it like this: Mill's *Logic* is primarily a theory of scientific knowledge (inference), essentially theoretical as compared with Whewell's book and still more so as compared with any treatise on any individual science; but it is primarily practical as compared with any treatise on pure logic or pure epistemology (which were, however, pretty much one and the same thing for Mill). As regards logical fundamentals, Mill leaned heavily on R. Whately even where he dissented from him.[9]

---

[9] Another revealing reference in the *Logic* (and in the *Examination of Hamilton*) is to Dr. Thomas Brown's *Lectures on the Philosophy of the Human Mind*, which, edited after Brown's death (1820), had a most successful career. The interesting point is that

Cautious and noncommittal as Mill was with reference to certain points of philosophical fundaments, modest as he was with reference to his personal contribution, in one respect he was neither cautious nor modest: exactly as in his *Political Economy*, in a manner that strikes us as curiously naïve, he cheerfully claimed an entirely impossible degree of finality for the results he expounded. He seems to say to us: why, I have collected and systematized the best ideas of this enlightened age, the principles either promulgated or conformed to by its ablest thinkers—what more can there possibly be left to do? His confident teaching fared in logic much as it did in economics.

Book I, 'Of Names and Propositions' (including Classification and Definition), in which there are passages almost suggestive of modern 'semantics,' and Book II, 'Of Reasoning' (Syllogisms; Deductive Sciences, which Mill holds are really inductive in so far as their premisses are derived by a process of induction from experience), cover ground on which Mill felt that the going was easy: for him who hardly ever looked below the surface, no serious problem arose to bar the way. He felt differently about the ground covered in Book III, 'Of Induction' (or generalization from experience, the core of scientific procedure and the core of Mill's performance). It contains the axiom of the uniformity of the course of nature, his theory of valid induction that is derived from it, his philosophy of causation, his famous 'four methods' (of Agreement, of Difference, of Residues, of Concomitant Variations), all of which is partly marred by faults of thought or exposition that can be explained on only one hypothesis: that even there, though writing on subjects that gripped him intensely, he wrote as he always did—in haste. But precisely because of this, substantial improvement can be effected in several cases without injury to his main positions. On the whole, there cannot be any doubt that Book III constitutes one of the great contributions to the theory of scientific knowledge. The many points of interest in the essentially subsidiary Books IV and V must be passed by, but Book VI, 'On the Logic of the Moral [Social] Sciences' is of first-rank importance to us. It should be perused together with Mill's older (pre-Comtist) essay on the method of economics (1836) that has been included in the volume on *Some Unsettled Questions*.

In order to do justice to this methodology of the social sciences, two things must be borne in mind. First, as an inevitable consequence of more fundamental shortcomings of Mill's general epistemology, there are many things in Book VI to which objections may be raised. But they do not impair its argument very much. Thus, his extension of the methods of the physical to the social sciences, including the concepts of scientific

---

this Scottish physician and philosopher, though he accepted sensationalism to a large extent, never abandoned 'intuitive' knowledge and had no empiricist theory of causation. The significance of Mill's strong recommendation of the book is not entirely destroyed by his qualifying objections to its argument.

law and of causation, are not nearly as objectionable as one might think because he watered down physical causation so radically as to make its extension to the social sciences practically harmless: his 'naturalism' was naturalism with its teeth pulled. Second, we must not forget that the fame and influence of Mill's work gave wide currency to his views so that much that reads trite and stale—like quotations from Hamlet—does so by virtue of his own achievement.

When all this is borne in mind, nothing remains but admiration. In a running battle with Comte, Mill triumphantly vindicated the actual procedure of economists while conceding—in fact, absorbing—all that should be conceded or absorbed. The standard method of economics was what he called the Concrete Deductive Method supplemented by the Inverse Deductive or Historical Method for research into historical changes of the social set-up as a whole. Had this been properly appreciated, the pointless later squabble of economists over induction versus deduction would have been avoided. The 'purely theoretical' set of problems was taken account of by his 'abstract or geometrical' method, the misuse of which for direct application to practical problems he made the target of scathing[10] criticism. The 'empirical laws,' nicely divided into uniformities of coexistence and uniformities of change, are assigned a place with which we can find but little fault. The impossibility of universally applicable, practical maxims was fully recognized as was *the necessity of studying actual human behavior in all its local and temporal varieties*—which should have taken off the curse from the economic man for all times. The *axiomata media* of his Ethology offered suggestions that are not fully exploited even now. The distinction that had to be fought for, sixty years later, between the problems of the effects that follow from a given cause under given social conditions and the problems of the 'laws' that determine those social conditions themselves is there. In fact, Mill unfolded a program that harnessed the purest of pure theory and the most concrete of institutional research into peaceful co-operation *and this without emasculating either*. Of course, Jevons reads fresh and stimulating even where he utters a platitude; Mill never reads fresh and stimulating even where he speaks valuable wisdom. That was the fault of his early training. But as regards this Book VI, though it contains nothing that was not said better later on—for example, by the elder Keynes—I conclude with advice to the reader to go back to it.

6. Pre-Marxian Socialism

In Chapter 2 above, we have said almost nothing about the socialism and the socialist groups or movements of the period. Painting in the large, we had hardly an opportunity for doing so. The omission can be repaired in a few words.[1] The second half of the eighteenth century produced a number of isolated socialist (or semi-socialist) writings but, before the French Revolution, nothing that can be called a movement. The French Revolution itself was bourgeois in origin, character, and ideology. The disintegration after 1791 of both its political set-up and its political thought was, however, associated with a literature that, though of very little importance in itself, was both indicative of a more than momentary socialist humor in a sector of the intellectual world of France, and instrumental in keeping it subterraneously alive during the Napoleonic regime. This provided a basis for the burst of propagandist activity, literary and other, of a socialist (or semi-socialist) nature that we observe in France until the advent of the second empire.[2] The revolution of 1848, though also bourgeois in origin, was quickly to show the existence of a sort of general staff of a revolutionary socialist army and even the existence of more or less definite plans for running a socialist state. Frightened to death, bourgeois groups did what Louis XVI could never be prevailed upon to do, that is, they suppressed the revolution by military force before it was too late. Thus, France holds priority in time as regards modern socialist literature; and among the business classes of all countries, the French business class was during that period the only one to face socialist revolution as a serious possibility. English Chartism, both in 1836-9 and 1840-48,[3] never amounted to anything like that, although it had a basis in early trade union organization that made it *more* serious in another and more fundamental sense. The only other socialist labor movement of importance was the German one that produced two organized parties: Lassalle's Allgemeiner Deutscher Arbeiterverein (1863) and Bebel's and Liebknecht's Socialdemokratische Arbeiterpartei (1869), which amalgamated in 1875.[4] The foundation and career of the First International (1864) is mentioned here only because of Marx's famous Inaugural Address.[5]

---

[10] This adjective is I think justified, though Mill's invariable courtesy, in some cases reinforced by filial respect, made him tone down his wording. It will read surprisingly but can be strictly proved that the methodological doctrine that Mill preached does not differ at all from the position eventually (though not at first) adopted by Schmoller.

---

[1] The interested reader has at his command plenty of sources of further information from which to supplement the jejune remarks that follow. He must remember that, from the standpoint of the aims of this book, we are not directly interested in social movements and their ideologies per se. In this particular case, brevity is excused in addition by the fact that our statements in this paragraph are not controversial. For general reference, Professor Alexander Gray's *Socialist Tradition* (1946) is recommended.

[2] The literary component of the movement supplied, however, part of the ideas of the *socialisme autoritaire* of Napoleon III, as has been mentioned already, just as socialist and semi-socialist workmen supplied part of the political support that raised him to power.

[3] The People's Charter itself, it should be remembered, was drawn up by William Lovett and Francis Place, the Bentham disciple, and was Benthamite and not at all socialist. In fact, its 'six points' embody nothing but radical parliamentary reform.

[4] Neither A. Bebel's nor W. Liebknecht's achievements come within the scope of this book. But the exploits of Ferdinand Lassalle (1825-64; the reader's attention is called to the biography by George Brandes, there are also several others) in sociological and economic analysis cannot go unmentioned though there will be no occasion to refer to them again. A highly cultivated man of brilliant abilities and indomitable energy, he was first and last a man of action whose intellectual, let alone scientific pursuits—though always attended to with zest—were always secondary to the excitements of a

[(a) *Associationist Socialism.*] Now, the one thing that is important for us to keep in mind is that the Marxist phase of socialist thought did not dawn before the beginning of the subsequent period.[6] The socialism of the period under discussion was non-Marxist and associationist.[7] This term is to denote all the varieties of socialist planning that adopt the principle of running production by workmen's associations—of social reconstruction through producers' co-operatives. Associationist socialism is, therefore, extra-scientific, because it does not concern itself primarily with (critical) analysis—as does Marxism—but with definite plans and the means of carrying them into effect. In addition, associationist socialism is unscientific because these plans involve assumptions about human behavior and administrative and technological possibilities that cannot stand scientific analysis for a moment. On both counts, Marx was quite justified in including associationist writers in his category of

---

fascinating life. An exception should be made, perhaps, for his most finished performance, *Das System der erworbenen Rechte* (1861), a brilliant piece of legal sociology that dazzled many a professional jurist. However, if we do make this work an exception and if we do assume that it was the product of genuine concentration, then we must also recognize that, along with very considerable philosophical and legal learning and strong critical ability, it displays lack of originality. His other writings display the same lack of originality, but unrelieved by learning, though still coupled with ability far and away above the common run of writers, socialist or other. The three most important economic publications, the *Arbeiterprogramm* (1863), the *Offenes Antwortschreiben* (1863), and *Herr Bastiat-Schulze von Delitzsch, der ökonomische Julian* (1864), are all of them brilliant pamphlets that embody, so far as analysis is concerned, a somewhat superficial but ably exploited Ricardianism—which accords with Lassalle's own view inasmuch as he described the only economics that seemed worth while to him as an 'immanent development' of Ricardo's teaching. This, by the way, is all his theory has in common with Marx's. To describe Lassalle either as a popularizer or as a disciple of Marx is quite erroneous. As regards agitatorial tactics and practical proposals, he was the very antipode of Marx—which is what caused the schism that impeded the progress of German political socialism until 1875 (Gotha Congress), when to Marx's infinite disgust, fusion was accomplished on a program that made large concessions to Lassalle's views.

[5] But no Marxist will take pride in this particular performance. Its contents reveal the effects of compromises that were perhaps inevitable but were of the sort that roused Marx's wrath when indulged in by other people. In fact, it was—as Marx himself pointed out with a mixture of humor and bitterness—thoroughly un-Marxist.

[6] Let me point out at once that, *so far as analysis is concerned*, the Marxist phase not only began but also ended with the subsequent period. This statement may seem surprising because we attach quite naturally high importance to the further revivals of Marxism in Russia and New York. But it will be substantiated below (Part IV, ch. 5, sec. 8).

[7] The term is convenient and I beg leave to use it, although I am aware of the awkwardness involved in using the same phrase in the same book in two entirely distinct meanings (psychological associationism—socialist associationism).

Utopian Socialists[8] and in fighting them bitterly. For he realized that they were discrediting serious socialism. By 1840, they had in fact succeeded in imparting to the very word Socialism a connotation of freakishness that helps to explain the attitude toward it that was specific to French economists:[9] to them, and not without reason, socialism came to mean two things, violence and nonsense. Some of the 'utopist' ideas were in fact unalloyed nonsense—in several cases, definitely pathological nonsense—and hardly any of them can be taken quite seriously, though an exception should perhaps be made in favor of L. Blanc (1811-82).[10] For us this is indeed not quite enough to warrant our neglecting them: freaks and dreams may yet enshrine sound pieces of analysis. Search undertaken in this spirit, however, yields but meager results. Not that we do not find sound reasoning and sound observation here and there; but most of what there is of it is trivial. Hence I shall mention only the outstanding examples of Robert Owen (1771-1858) and Charles Fourier (1772-1837),[11] who with Saint-Simon shared in a huge wave of American enthusiasm.

---

[8] Marx described as utopian any form of socialist thought but his own, which he called 'scientific.' The defining characteristic of *his* scientific socialism is, however, the scientific proof of the inevitability of socialism, so that with him the phrase 'utopian' should not have meant the same as 'not serious,' though it did. By a 'bourgeois economist,' Marx denoted an economist who fails to see this inevitability or, much more restrictively, an economist who believes in indefinite survival of the capitalist order. If the reader observe that these definitions do not coincide with the meanings usually attached to the terms, he will save himself many misunderstandings.

[9] Engels attributed the fact that Marx chose Communist instead of Socialist for use in the title of the Marx-Engels manifesto to Marx's dislike of a term that had acquired a flavor of 'respectability.' It is more likely, however, that Marx disliked it because it had acquired a flavor of oddity.

[10] Louis Blanc (*Organisation du travail,* collected articles first published in 1839) was no doubt also an associationist of humanitarian and rhetorical propensities that earned him semi-benevolent contempt from later critics, bourgeois and socialist. But his proposals differed from, say, Owen's by an element of practicability that shows especially in the more than supervisory role assigned to the bureaucracy (state). This element suggests possible influence upon Lassalle. Blanc once made the proposal that emerged again with some socialists, in and after 1930, to hand over to workmen factories that had closed down. Distribution according to the principle 'to everyone according to his needs' was a pet idea of his (though not adhered to), and he may be responsible for its currency among the socialists of his and a later time.

[11] The interested rearder will find bibliographies of (and on) both in any work of reference. As regards Owen, there was good reason for the emergence of a large literature about him for, quite independently of his plans and experiments of the New Harmony type, his ideas as well as his practice were of seminal importance in very many different ways that had little to do with one another. Thus, his fundamentally paternalistic measures at New Lanark created a model for the labor policy of the modern large-scale concern and, more important than this, initiated a new attitude toward wage questions. His emphasis on the value of strikes and trade unions versus political action makes him a classic in the history and theory of trade unions. His ideas on artisans' co-operatives have made him the patron saint of one of the significant movements of that and a later time. Not only was 'moral grandeur' (Torrens) his but

This is our opportunity for a glance at the American (and not only U.S.) Social-Science Movement.[12] The word Science, when used in connection with this movement, must be taken in a sense akin to the one it carries in the phrase Christian Science rather than in the usual one, for there was little genuinely scientific effort. A society that produces a comparatively prosperous stratum more quickly than it produces a cultural tradition is open to unbalancing infiltrations of ideas, even apart from the influence of physical immigration. A small number of people enjoyed leisure—'lettered ease' it was with some—and had open minds, which compensated shrewdness in business by enthusiasms and radicalisms, as generous as they were uncritical, in everything else. One of the most characteristic of these enthusiasms was the layman's enthusiasm for 'science'—and especially for social alchemy because, to the untrained mind that vibrates with unemployable energies, the real thing is not half so exciting as is the fake. This is the sociology of the movement. Its real importance for the impulse it gave to American economics and sociology is as difficult to appraise as is the real importance for serious research of the romanticist movement in Europe, of which, in fact, the social-science movement may be interpreted as the specifically American counterpart. I can see no relation between it and the performances that eventually established both economics and sociology in the United States, and am inclined to think that its petering out around the epoch of the Civil War was more favorable to social research than was its emergence. But the reader will easily see all that can be adduced for the opposite view.

But how can we account for the presence of sponsors of associationism whose claims to being taken seriously are not open to doubt? Well, for one thing, there is the influence of the literary fashion that the French associationists certainly succeeded in creating. For another thing, there is the support that associationist socialism as a plan for comprehensive social reconstruction derived—quite illogically, of course—from the actual co-operative movement and its literature. Both these elements will, I think, account for the asso-

---

also, within the sphere of thought and action defined by our examples, sound and even shrewd common sense (as his own business success suffices to prove). But as soon as he stepped out of this sphere, which was truly his own, his complete lack of analytic ability of the more subtle kind showed up immediately. Neither his ideas of the Labor Note that was to replace 'money' nor his ideas of an Equitable Labor Exchange are nonsense in themselves, but he just did not know how to protect his case against the most obvious criticisms.

As regards Fourier, the reader is referred to the one really enlightening item I have come across in the large literature about him: E. S. Mason's 'Fourier and Anarchism,' *Quarterly Journal of Economics* (February 1928). Two points must be made: first, Fourier did base his plan (of which the Brook Farm colony was the most famous embodiment) upon an elaborate analysis of human nature, in general, and of the nature of society, in particular, but it was all conceived in the worst style of eighteenth-century speculation; second, his *phalanstère* organization has but a qualified claim to being called socialist, and it is amusing to note that with the ignorance of actual conditions that characterizes so many of those prophets, he actually reserved for interest and profits a larger relative share than goes to them, on the long-run average, in capitalist reality.

[12] The U.S. branch of it has been described in L. L. and J. Bernard, *Origins of American Sociology: The Social Science Movement in the United States* (1943).

ciationism of Lassalle—his scheme of productive associations that were to be subsidized by the state and, by virtue of this advantage, to compete private industry out of existence.[13] But there is something else: to Marx and to many of us, associationism may be nonsense; but it was not nonsense to the Benthamite mind. In fact, a glance at the utilitarian views on the human mind and on the nature of social relations suffices to show that, once these assumptions concerning the quality—and substantive *equality*—of individuals are granted, associationist hopes cease to be absurd. And this accounts for the cautious associationism of J. S. Mill.[14]

[(b) *Anarchism.*] If we extend the principle of associationism to the political sphere and visualize the dissolution not only of industrial concerns into workmen's co-operatives but also of national states into voluntary 'communes,' we have Anarchism—of which by far the most articulate, but not the most orthodox or most consistent, exponent was P. J. Proudhon.[15] Here we are interested neither in his political anarchism nor in his philosophy, which he himself described as Hegelian, though I find it more easy to link it up with Fichte's. And we are interested in his economics only because it affords an excellent example of a type of reasoning that is distressingly frequent in a science without prestige: the type of reasoning that arrives, through complete inability to analyze, that is, to handle the tools of economic theory, at results that are no doubt absurd and fully recognized as such by the author. But the author, instead of inferring from this that there is something wrong with his methods, infers that there must be something wrong with the object of his research, so that his mistakes are, with the utmost confidence, promulgated as results. Proudhon's *Système des contradictions économiques ou philosophie de la misère* (1846) is the outstanding monument to this frame of mind. He was, among other things, unable to produce a workable theory of market value. But he did not infer: 'I am a fool,' but: 'Value is mad' (*la valeur est folle*). Marx's scathing criticism (*Misère de la philosophie,* 1847) was fully deserved, though not well aimed in every respect. It should be observed, however, that Proudhon's claim to be called an anarchist in his own sense is questionable. For though, repeating an eighteenth-century phrase, he described property as theft in the pamphlet that founded his fame (*Qu'est ce que la propriété?*, 1840), his big idea was gratuitous credit rather than abolition of private property: loans free of interest to be issued in the notes of a public bank so that everyone might have access to means of production and become a proprietor—an idea that was to be revived by some latter-day projects of Social Credit.

---

[13] Moreover, though the man is to be taken seriously, it is fairly open to question how far his scheme is. Nobody can study that life of high endeavor and tragic failure without becoming aware of the fact that he is studying an important aspect of the German tragedy. In other words: Lasalle was a born political leader, conscious of superlative powers, and there is as little point in proffering the all-too-easy objections to his plan as there is in pointing out logical weaknesses in Disraeli's early thought. The real counterargument would have been to appoint him to cabinet office. But this is precisely what Prussia was congenitally unable to do.

[14] On the extent to which J. S. Mill should be considered a socialist, see below, ch. 5, sec. 1. Mill may have influenced Lassalle.

[15] Of the Proudhon literature, I mention only a work of indubitable scholarly quality, though there are several others that come within this category: Karl Diehl's *P. J. Proudhon, seine Lehre und sein Leben* (1888-96). In Joseph Proudhon (1809-65) we behold a phenomenon that is as rare among socialist thinkers as are horse-drawn vehicles in New York: a real, live proletarian. He was self-taught and this lack of training shows on every one of his many pages. Some of his ideas had been previously published by English socialists. But it is practically certain that he did not know of them.

Mikhail Bakunin (1814-76), Marx's pet aversion, has no place in a history of analysis, as he himself would have been the first to admit.[16] But there was another anarchistic communist or communistic anarchist who did present a piece of analysis: Weitling, the founder of 'Communia' in Wisconsin.[17] His particular plan does not concern us, but his theory of poverty does because it seems to enjoy a kind of immortality: it always turns up again. It is of the type of social criticism that, like Henry George's or F. Oppenheimer's, traces poverty to private property in land.[18] According to Weitling, there is no objection whatever to private property in other means of production and to private-business management of industry as long as there is free land accessible to everyone—all the trouble arises and *any* kind of property becomes a curse only when land becomes scarce, hence an object of property rights. The lessons I want the reader to learn from this are two. The first is one in the sociology of economic thought. Even so critical a thinker as Locke had no compunctions about the analytic value of the proposition: God gave the earth in common to all men. And this idea asserted itself in all ages, though in very different forms, even in writings that purport to present results of strictly empiricist thinking. The other lesson is one in faulty analysis. In many cases, actual and possible, the institutional structure of the agrarian sector may indeed be responsible for misery of the masses in the sense that their standard of life is lower than it would be with a different structure. In order to prove this possibility, we need only imagine a state of things in which land is so plentiful as to be capable of being a free good but is monopolized, in the technical sense of the term, by a single land-holding corporation that sets a monopoly price on its use. Cases somewhat more realistic than this then become verifications for the quite different proposition that the mere fact of private property in land reduces, of necessity, total real wages. This general proposition can be refuted by a rather elementary argument, which anyone is bound to encounter if he takes a few minutes to consider the question why private property should have that effect. But nobody who has this bee in his bonnet ever takes these few minutes, and if he did he would—like Rousseau in the matter of miracles—go mad rather than give up the idea that feeds his emotional life. And some such 'bee,' though not necessarily this one, is the most cherished possession of a distressingly large number of the people who write on economic subjects.[19]

---

[16] The best-known communist thinker of the subsequent period, P. A. Kropotkin (1842-1921), is a different case. He made non-negligible efforts at analysis and his sociology of law is not without interest, though sufficiently so to warrant his exclusion from our report. Of course, for a history of economic and political thought (as contrasted with analysis), both he and Bakunin are of immense importance. And still more so for a sociology of economic and political thought. How tsarist society came to produce—in its higher and highest circles—revolutionary communism is in itself a fascinating problem: a crack cavalry regiment was not the worst of nurseries for communist impulses.

[17] Wilhelm Weitling (1808-71), *Die Menschheit wie sie ist und wie sie sein sollte* (1838); *Garantien der Harmonie und Freiheit* (1842).

[18] Not all agrarian socialists do this, of course.

If we leave the national state untouched and organize economic activity not into small free groups that on principle are self-sufficing but into vocational groups that are more like (though not necessarily quite like) the artisans' and merchants' guilds of the Middle Ages, we get the idea of the Corporative State. Such an idea was developed by Fichte and by many Catholic writers such as Baader. The main point is that these plans do not assume that the state should manage the corporations but rather the other way round:[20] they should hence not be identified with modern fascism; unlike the latter, they are anti-*étatiste* in conception. None of these writers bothered much about economic aspects. It is their cultural vision that is interesting. From our standpoint, there is no comment to be made.

In this connection, we may notice in passing the work of Karl Marlo,[21] an author who has been much commended by nonsocialists such as Roscher and Schäffle. Not a thorough-going socialist, he planned to sail between the Scylla of liberalism and the Charybdis of communism, to insure true equality and true liberty and so on by means of a large amount of nationalization of industry and of corporative organization for the part of economic activity that is not to be nationalized. A strong sense of responsibility that accounts for the bourgeois praise and is quite surprising in a man who was primarily a planner shows in Marlo's concern about the productivity of his system, about population, and about insurance. But the only point that interests us here is his analysis of competitive capitalism. On the one hand, he drew a picture of the condition of the working class that was as gloomy as was Engels'.[22] On the other hand, he attributed this condition not to the historically unique conditions that prevail frequently, though not necessarily, in the earlier stages of capitalist evolution but to the inherent logic of the capitalist system that, if allowed to operate, will always and increasingly depress labor's lot. We observe, first, that the factual picture is biased even *ex visu* of about 1850. For even then statistics were available that any layman could have read to prove that talk about enslavement and starvation, and still more talk about *increasing* misery of the masses, lacked foundation in fact except so far as sporadic instances were concerned. We observe, second, that the analytic effort is biased in the same direction. For Marlo's analysis of competitive capitalism entirely failed to consider the obvious alternative to the proposition about enslavement and systematically omits to take account of those mechanisms in the capitalist process that tend to work the other way. But this systematic bias is evidently not like the bias of an index number or the bias in a particular source of information. It is typically the bias of ideological delusion, the kind of bias that springs from a writer's extra-analytic convictions and is impervious to either fact or argument. Refuting fact and argument would be met by moral indignation.

---

[19] Some readers may wonder why, speaking of communism, I do not mention Cabet. But there is nothing to be said about him from our standpoint.

[20] At least, if certain co-ordinating or supervisory functions are left to government, the corporations are to retain a large measure of autonomy.

[21] *Nom de plume* of Karl G. Winkelblech (1810-65): *Untersuchungen über die Organisation der Arbeit* . . . (1848-59).

[22] This is our opportunity to mention again a book that influenced social thought, in Germany at least, far beyond the circle of socialist orthodoxy: Friedrich Engels, *Die Lage der arbeitenden Klasse in England* (1845; English trans. 1887).

This is the point that made it worth our while to mention Marlo at all. Though individually of no great importance or influence, he was one of the many writers who helped, around the middle of the nineteenth century, to crystallize the ideology of the capitalist process. The main traits of this ideology had all emerged by 1776. They gained in definiteness through the efforts of writers such as the Ricardian socialists, Engels, Marlo, and many others in the next three-quarters of a century or so. Then the picture had become fixed. That is to say, it had, for considerable sectors of both the economic literature and the public, reached the status of 'as-everybody-knows' and was no longer questioned but was taken for granted by an increasing number of people. It was, in the thought of these people, substituted for the capitalist reality that increasingly diverged from it. It was the picture that Marx analyzed. It is the picture on which sophomoric radicalism feeds to this day.[23]

[(c) *Saint-Simonist Socialism.*] We could go on indefinitely but, having learned from three examples all that is to be learned for our purpose from this literature, we should not gain sufficiently by doing so.[24] One name, however, must be added, that of Saint-Simon.[25] In the main, this pathological genius—Émile Faguet's *fou très intelligent*—affords only another example that illustrates the difference between a man's importance for a history of economic thought and his importance for a history of economic analysis. Saint-Simon's name stands in the history of economic thought because of a message of a semi-religious character and because disciples turned this message—not without altering it—into the creed of a sect. Much has been written about Saint-Simon's posthumous success: not only in France but also in England, Germany, and especially in the United States and in Latin America, Saint-Simonist groups emerged and even a Saint-Simonist intellectual fashion of much wider range. But the groups consisted of small nuclei that quickly repelled serious members and brought discredit upon themselves by freakish developments of the creed. Around these nuclei there were more numerous adherents whose allegiance was not very close and was chiefly phraseological. As to the question how much importance should be attached to the intellectual fashion, men will, as in all similar cases, differ till doomsday. The fashion itself is explained as soon as we visualize the two salient features of the message that combined to produce something that was not to be had from any other creed: on the one hand, its glowing humanitarian optimism; on the other hand, its glorification of 'science' (technology) and of industrialism. Where other humanitarians were sour and doubtful about what sort of a future capitalist industry

---

[23] There should really be little difficulty in realizing that Crystallization of Ideologies is the only explanation for the existence of honest belief in the misery, helplessness, and frustration of the working class at a time of the political and economic dominance of the labor interest. Examination of the rationalized arguments only serves to strengthen this diagnosis. But crystallized ideologies that satisfy deep-seated urges defend themselves with desperate energy.

[24] A man who might have served us just as well as did Weitling, though less so than the more serious Marlo, is Charles Hall, *The Effects of Civilization* [i.e. Technological Progress], 1805. The problem to be discussed with respect to him, similar though it is in all other respects, would display another, though cognate, aspect that is not without importance to the social psychology of the social sciences. It may be put by means of the following question: since by all accounts this man was an able physician, how was it possible for him to use, in the field of social criticism, modes of thought that would have prevented him from passing his M.D. exams? I do not mean his recommendations, but the formal properties of his reasoning and his handling of facts. Another such man is J. F. Bray, *Labour's Wrongs and Labour's Remedy* (1839; London School Reprint, 1931). All I wish to say about him is that Marx should not be insulted by its being said that Bray anticipated him in any point:

---

any argument that works with exploitation must bear misleading witness to some affinity with Marx. The work of F. Huet (*Le Règne social du Christianisme*, 1853), whose proposal of division among the young generation of *biens patrimoniaux*, land especially, as they are released by death, suggests that Saint-Simonist ideas found favor also in Catholic centers. The 'Ricardian' socialists will be briefly considered later. On Engish Christian socialists, see C. E. Raven, *Christian Socialism*, 1848-54 (1920), and L. Brentano, *Die christlichsoziale Bewegung in England* (1883). See also, J. O. Hertzler, *History of Utopian Thought* (1923).

[25] Claude-Henri de Rouvroy, Comte de Saint-Simon (1760-1825) was a Rouvroy and therefore of the—genealogically speaking—best but also most degenerate blood of France; *Oeuvres choisies* (1859); biography by M. Leroy (1925); many works on the Saint-Simonist 'system' of thought and the Saint-Simonist sects, e.g. S. Charléty, *Histoire du Saint-Simonisme*, 1825-64 (1896). On an aspect of special importance for us, see E. S. Mason, 'Saint-Simonism and the Rationalisation of Industry,' *Quarterly Journal of Economics* (August 1931). The question which of his writings I should recommend to the reader embarrasses me greatly: it must be answered quite differently for men of different interests and tastes. As for myself, I know only those contained in the *Oeuvres choisies*. In a general way, I believe that economists will profit from a perusal of *Du Système industriel* (1821) more than from a perusal of his last and most famous work, *Nouveau Christianisme* (1825), which falls somewhat out of line with the rest and contains chiefly preachings of an utilitarian character—increase of the welfare of the most numerous and poorest class and so on—that are more Benthamite than Saint-Simonian. Perhaps I should also mention Bazard's *Exposition de la doctrine de St. Simon* (1830), which is remarkable for clearness. Nothing need be said, for our purposes, of his followers (Enfantin and Bazard were the most important) beyond the general comment on them in the text.

would provide for humanity at large, Saint-Simon gave comfort. Where other enthusiasts of industrial progress were harsh and unsympathetic, he preached the golden age for all. It was this combination of features that made Saint-Simonism so popular, for a time, with financiers of the promoter type such as the brothers Pereire of Crédit-Mobilier fame. But can the reader be so thoroughly imbued with intellectualist misconceptions as to believe that, without Saint-Simon's teaching, the Crédit Mobilier would not have been founded and managed exactly as it actually was, and would not have crashed exactly as it actually did?

There is something else, however. Saint-Simon's vision was not implemented by analytic work but nevertheless it is relevant for us in two respects. First, there is a conception of social change that may be said to adumbrate an economic interpretation of history. Saint-Simon felt the breakdown of the *ancien régime* and the advent of a new epoch with a pungent sense of reality—to use William James's phrase—that could not have come so naturally to anyone who was not a Rouvroy. Simplifying this into a breakdown of the feudal world and the advent of the epoch of industrialism *under pressure from economic (technological) developments*, he grasped some essentials of the eternal flux of social organizations and, within it, of the struggle of economic classes, his idea being that he was to lead humanity out of this struggle by means of the wonderful achievements of 'science'—rant, partly, but rant interspersed with flashes of profound understanding.[26] Second, there is a perception or a glimpse of the true nature of the capitalist process that acquires particular importance from the fact that neither Marx nor his bourgeois peers had it: Saint-Simon saw the pivotal importance of industrial leadership. He confused, it is true, the entrepreneur with the 'scientist' who devises new technologies. And he used his vision in the construction of a new form of social organization and not, as Marx would have done in his place, in any attempt to explain social processes as they are. Still, he did introduce a new factor that might have revolutionized 'classic' economics and might have put an end to analytic—as distinguished from normative—equalitarianism. However, nothing resulted from his vision except that his socialism—if indeed his 'system' can be called socialist at all—was hierarchic[27] and not equalitarian. And economists completely failed to exploit this mine.

---

[26] I do not think, however, that this impairs materially the case for Marx's originality as regards the economic interpretation of history. For I find it difficult to conceive that anyone who had not had the idea himself could have been inspired to construct it from the suggestions proffered by Saint-Simon's writings. At worst, Saint-Simon was in this respect a forerunner in the same sense as Buffon and Erasmus Darwin were forerunners of Charles Darwin.

[27] This comes out very nicely in a letter addressed by Enfantin and Bazard to the President of the *Chambre des deputés* in 1830, a reprint of which the reader will find in Professor Gray's *Socialist Tradition*, p. 168. Let me add one more point: Saint-Simon, too, spoke of 'association' but this has nothing to do with the associationism discussed previously.

ACCORDING TO PLAN, we shall survey the general layout of this period's analytic economics in Chapter 5, taking up headquarters in J. S. Mill's *Principles*. The review of the more important men and groups in the present chapter is for the benefit of readers who are unfamiliar with any but the greatest figures. It will not contain more names than are necessary for a general orientation. Others will be introduced as we proceed.

1. THE MEN WHO WROTE ABOVE THEIR TIME

We have emphasized the relative maturity that economics gained during the period under survey. Its relative immaturity might be measured by the number of important performances, the powerful originality of which was recognized later but which the profession completely, or almost completely, failed to recognize at the time. This happened in the cases of Cournot and of the various writers, especially Dupuit, Gossen, and Lloyd, who discovered the marginal utility principle. We shall transfer them to Part IV, merely observing for the moment the melancholy implications of this neglect: it shows a lack of alertness and of purely scientific interest among the economists of the period that goes far toward explaining why economics did not advance more quickly.[1]

---

[1] We may adduce mitigating circumstances, but substantially the indictment stands. Cournot was not unfavorably placed for getting a hearing. If he failed to get it, this was wholly due to the mathematics in the book. But precisely—what sort of a profession was this that laid aside a work because it was a little difficult of access? Dupuit elicited at least some criticism. Gossen was unfavorably placed and, if he did nothing to circulate his book among professors, the latter's sin may have been venial. But

In addition, there were other performances that fared a little better but also proved to be above their time in the sense that they failed to receive the attention and exert the influence which, enlightened by hindsight, we should deem appropriate. Of these, the most noteworthy are the writings that developed the marginal productivity principle. Since some leaders of the day occasionally did move within its orbit,[2] we shall at once make our bow to two early exponents of that principle who are particularly important, Longfield and Thünen. And I shall append a notice of still another man who wrote above his time, John Rae.

Mountifort Longfield (1802-84) was a lawyer by training and the first incumbent of the chair of political economy—a foundation of Archbishop Whately's—at Trinity College, Dublin. He also wrote on the Poor Law and other subjects, but the only publication of his we need notice is *Lectures on Political Economy* (delivered 1833, publ. 1834, London School Reprint 1931). Anyone who cares to glance at this book will readily understand why, in spite of its merits of exposition and matter, he failed to make a mark, so that he had to be unearthed, along with others, by Professor Seligman in the justly famous article 'On Some Neglected British Economists,' *Economic Journal*, 1903,[3] for which all students of the history of economics have every reason to feel lasting gratitude. But this neglect is readily understandable only if we realize what it is that will impress professional opinion and what it is historians of economics usually look for, namely, on the one hand, a man's views on the practical issues of his day and, on the other hand, the way in which he handles the theoretical tools that are common currency in his day. New ideas, unless carefully elaborated, painstakingly defended, and 'pushed' *simply will not tell*. Longfield's case illustrates so well the important question 'what takes effect and how and why,' because Longfield did not fail to keep contact with Ricardian teaching—he gave Ricardians every opportunity to be led to a more perfect analysis gently and without any violent break—and because he did find successors: he really founded a local 'school' (on this, see R. D. Black, 'Trinity College, Dublin, and the Theory of Value, 1832-1863,' *Economica*, 1945). His successor in the Whately chair, Isaac Butt (*Rent, Profits, and Labour*, 1838),

---

W. F. Lloyd was 'Student of Christ Church and Professor of Political Economy' at Oxford. His argument on marginal utility was quite straightforward and there was nothing deterrent about it. Several writers brushed against it, e.g. Senior. It must have become known to a number of people. The only construction that it is possible to put upon the fact that Lloyd's argument exerted no influence is that the economists who read it were blind to the analytic possibilities enshrined in it.

[2] Later on, it will become clear to the reader that it would have been quite impossible for them not to do so. Also, it will be explained later why I do not think that they, Ricardo especially, should be credited with more than is implied by the phrase in the text.

[3] Reprinted in E. R. A. Seligman, *Essays in Economics* (1925), ch. 3.

was his professed disciple and—correctly as I believe, if we consider pure theory only—put him on the same level as A. Smith.

Longfield's merits may be summed up by saying that he overhauled the whole of economic theory and produced a system that would have stood up well in 1890. Among other things, his argument against the labor theory of value is one of the best ever penned. However, we must confine ourselves to his two original contributions. He was one of those who anticipated the essentials of Böhm-Bawerk's theory (by making the 'roundabout' process of production the pivot of his analysis of capital). And he presented a reasonably complete and reasonably correct theory of distribution based upon the marginal productivity principle, not only the marginal cost principle. That is to say, he explained both 'profits' (return upon physical capital) and wages in terms of the contributions to total product that result from the addition to the productive set-up of the last element of capital (tools) or labor. Thus at least it seems fair to interpret him, though in details his argument is open to many criticisms (among other things he failed, as did many writers even after 1900, to distinguish clearly between the last laborer added and the least efficient laborer). The argument is still worth reading because it shows nicely the operations by which economists' minds paved their way toward the use of the general marginal principle. But we cannot stay to work this out.

Johann Heinrich von Thünen (1783-1850), the man whom A. Marshall professed to have 'loved above all my other masters' (*Memorials of Alfred Marshall*, 1925, p. 360), meant, of course, much less to his age than did Ricardo. But this is due to the latter's brilliant advocacy of policies. If we judge both men exclusively *by the amount of ability of the purely theoretical kind* that went into their work, then, I think, Thünen should be placed above Ricardo or indeed above any economist of the period, with the possible exception of Cournot. He was a North German Junker and followed the typical profession of the North German *Junkertum* (the correct translation is 'gentry'): for most of his life (after having completed his education at an agricultural college supplemented by two semesters at the University of Göttingen), he farmed the indifferent soil of his medium-sized estate, just about managing to make both ends meet and, sacrificing everything else, to keep up his intellectual interests in wintertime. This practical farmer was a born thinker, however, and quite unable to supervise the teams that ploughed his land without working out the pure theory of the process. His thoughts roamed toward wide generalizations from an early age but, first of all, he was an agriculturist, schooled in the ideas of Thaer, and an agricultural economist. As such he did enjoy recognition in his own country. Later on, he was also recognized more generally but in a peculiar way. Roscher, for example, considered Thünen's work to be one of the most important that had been written in Germany in the field of exact economics. Yet he entirely failed to grasp its true meaning. Reviewers were complimentary. Yet none of them understood the work except the part of it that is listed below under (III). For the rest Thünen, unlike Cournot, *never* came into his own. For though he continued to be quoted, the marginal productivity theory of distribution was independently rediscovered later, and his message was fully understood only at a time when all that would strike the reader was its shortcomings. The first volume of his *Der isolierte Staat in Beziehung auf Landwirthschaft und Nationalökonomie* was published in 1826 (2nd ed., 1842); the first part of the second volume, in 1850. The rest of the second volume and a third were published, from unfinished but well-advanced manuscripts, by H. Schumacher in 1863. There is a new edition with an introduction by Heinrich Waentig in *Sammlung sozialwissenschaftlicher Meister* (vol. XIII, 1910). The third volume contains 'Principles for the Determination of the Rent of Land, the Optimal Period of Rotation, and the Value of Timber of Different Ages for Firs' [This is a literal translation by J. A. S.]. The standard biography is also by Schumacher (1868), but the reader finds the relevant data in Professor E. Schneider's article 'Johann Heinrich von Thünen' in *Econometrica*, January 1934.

Thünen's contributions may be summed up as follows. (I) He was the first to use the calculus as a form of economic reasoning. (II) He derived his generalizations, or some of them, from numerical data, spending ten laborious years (1810-20) in carrying out in detail a comprehensive scheme of accounting for his farm in order to let the facts themselves suggest the answers to his questions. This unique piece of work, undertaken in the spirit of the theorist, makes him one of the patron saints of econometrics. Nobody, before or after, ever understood so profoundly the true relation between 'theory' and 'facts.' (III) Nevertheless, this man who was so fact-minded knew at the same time how to frame ingenious and fertile hypothetical schemata. His peak achievement in this art is his conception of an isolated domain of circular form and uniform fertility, free from all obstacles to or special facilities for transport, with a 'town' (the only source of demand for agricultural products) in the center. Given techniques, cost of transportation, and relative prices of products and factors, he deduced from this the optimal locations (which under those assumptions would be ring-shaped zones) for the various kinds of agrarian activities—dairying, forestry, and hunting included. A theory of rent, in some points superior to that of Ricardo, results as a by-product. Though many people objected to such bold abstraction, this was the part of his work that was understood and recognized in his time. For us, it is important to realize its brilliant originality. Ricardo or Marx (or whoever it is among the theorists of that period who holds the place of honor in the reader's scale) worked on problems that presented themselves from outside by means of analytic tools that had been forged before. Thünen alone worked from the unformed clay of facts and visions. He did not rebuild. He built—and the *economic* literature of his and earlier times might just as well not have existed at all so far as his work is concerned. (iv) In quite the same spirit, he was the second (the first was Cournot, by date of publication at least) to visualize the general interdependence of all economic quantities and the necessity of representing this cosmos by a system of equations. (v) He introduced explicitly the tool of analysis, actually used of course by Ricardo, that may be termed the 'steady state' of the economic process—Marshall's long-run normal—that was akin to statics rather than to the stationary state of 'classical' theory. (vi) As fully as Longfield, and somewhat more correctly, he developed a marginal productivity theory of distribution, at least for the relation between capital and labor, interest and wages. But the fundamental idea itself (which he correctly puts, in words, in terms of partial differential coefficients, Waentig edition, p. 584) is almost a secondary element in the wealth of problems he grouped around it. No idea of these can be conveyed. Instead we must touch on another point, not because it is worth our while in itself, but because it has attracted attention beyond its deserts: Thünen's famous formula for the 'natural wage.' He must have thought a lot of it, because he had it engraved upon his tombstone.

For simplicity, consider a one-year productive process, the only expense of production being wages. Call the dollar value of the national net product p, the total pay roll w, so that total profits (which Thünen, like others, identified with interest) are $p - w$, and the rate of profits (interest) is $\frac{p-w}{w}$. Suppose that the wage receivers spend a fixed amount, a, per year, investing the rest, $w - a$, at the current rate of interest, $\frac{p-w}{w}$. On this investment, they will evidently earn $\frac{p-w}{w}(w-a) = p - w - \frac{ap}{w} + a$. If this expression is to be a maximum, we must have[4] (p and a being treated as constants),

$$\frac{d(p - w - \frac{ap}{w} + a)}{dw} = -1 + \frac{ap}{w^2} = 0$$

from which follows Thünen's formula, $w^2 = ap$, or $w = \sqrt{ap}$. This wage would maximize workers' income from investment. The idea is not without interesting suggestions and might be used among other things in certain schemes of profit sharing. But, of course, this wage is not 'natural' in the sense that the free-market mechanism tends to produce it. The formula does not embody Thünen's theory of wages. Nor is it an essential part of it. The wildly unrealistic assumptions should not, however, prompt us to declare the argument wrong. Under its assumptions it is quite right.

---

[4] In order to have a maximum and not a minimum, it is further necessary that the second derivative be negative. But this is all right, since it equals $\left(-\frac{2ap}{w^3}\right)$, a, p, and w being essentially positive.

John Rae (1796-1872; not to be confused with the other John Rae mentioned in this book, the biographer of A. Smith), a Scotsman whose intellectual refinement—he had emerged from the Universities of Aberdeen and Edinburgh as a good classical scholar and mathematician and as a biologist and physician who was at least half trained—and nervous sensibility made him a failure at everything he touched. From 1821 on, he roamed about in Canada, the United States, and other countries, the Hawaiian Islands included, where he had to rough it (two spells of schoolmastership being by far the most congenial of all the employments he tried) until, shortly before his death, he drifted with broken masts into the haven of a friendly house in Clifton, Staten Island. Yet, all the time, he also struggled with what under the circumstances was the greatest misfortune of all, an unmanageable wealth of ideas on the subjects of biology, philology, ethnology, aeronautics, and what-not—all, or most of them, parts of a grandiose plan, conceived in his youth, of a 'philosophical history' of humanity. Up to this point the reader will feel that he is recognizing a well-known type. He is wrong. For one achievement, complete and workmanlike, yet of striking power, refutes the idea the reader may have conceived. This achievement happened to be in our field. In vision and originality, Rae far surpassed the economists who were successful.

The *Statement of Some New Principles on the Subject of Political Economy Exposing the Fallacies of the System of Free Trade and of Some other Doctrines Maintained in the 'Wealth of Nations'* was published in Boston in 1834. In this note we shall try only to appreciate the nature and importance of the performance and record its fate.

Rae had not more than a saving knowledge of economics. It is evident that he owed such training as he had mainly to the work he attacked. But this he had mastered in all its ramifications, premisses, and implications as only a kindred spirit can, and after having developed his own ideas in constant reference to it, he proceeded to erect a structure similarly conceived. For it is this that we must see in his work: another *Wealth of Nations* or, more correctly, something that with ten additional years of quiet work, graced by an adequate income, could have grown into another—and more profound—*Wealth of Nations*. It follows that it would be quite inappropriate to dwell on the many minor good things the work contains—a few will be mentioned in the proper places. The essential thing is the conception of the economic process, which soars above the pedestrian view that it is the accumulation of capital per se that propels the capitalist engine. The conceptual apparatus developed in the First Book is glorified by the new vision but not otherwise remarkable and need not detain us any more than needs the Third Book, which deals with 'the operations' of that imaginary entity, the 'legislator.' Naturally, Rae's dissent from Smith's anti-*étatiste* views will primarily interest the student of economic thought. The Second Book, however, has attracted most of the attention that later economists devoted to the work. It may be called a theory of capital, conceived in unprecedented depth and breadth. To say that it presents the whole of Böhm-Bawerk's theory is to display inability to understand Böhm-Bawerk. But two cornerstones of the latter's structure—one of them also a cornerstone of Senior's—are in fact there: the proposition that 'lengthening' the process of production (postponement) will usually increase the physical amount of final product (ch. v), and the proposition that 'the actual presence of the immediate object of desire' will give to it, in our valuation, a decisive advantage over an exactly similar object that is expected to become available at some future date, even if this expectation be perfectly certain.

As a rule, a work presenting novel ideas will not elicit response if it lacks the support which comes from being written by a well known author. We ought, therefore, to be surprised at the response it met with rather than at the fact that it did not meet with more. J. S. Mill noticed it, and—perhaps in consequence of this—there was an Italian translation in 1856. How, then, can it have been necessary to 'discover' Rae, as Professor Mixter rightly claimed it was? (Cf. C. W. Mixter, 'A Forerunner of Böhm-Bawerk,' *Quarterly Journal of Economics*, January 1897 and 'Böhm-Bawerk on Rae,' ibid. May 1902, and the same author's (rearranged) edition of Rae's work under the title *Sociological Theory of Capital*, 1905, prefaced by the biography from which the data above about Rae's life have been taken.) The answer might serve as a motto for a chapter of the sociology of science. J. S. Mill was invariably fair and even generous. Sensing the quality of the work, he was glad to mention it in a friendly spirit, not only to accept from it a phrase that happened to fit into his line of thought ('effective desire of accumulation') but also to quote it copiously (Book I, ch. 11). He even went so far as to compare Rae's performance on accumulation with Malthus' performance on population. And all this, written in what was to be for forty years the most influential textbook of economics, was insufficient to introduce Rae to the profession or to rouse any curiosity concerning the rest of his book! Or, alternatively, if this impression is wrong and any considerable number of Mill's readers did take it up, there was not one among them to realize its true importance. However, it may be of some significance to note that Senior knew the book (see 'John Rae and John Stuart Mill: a correspondence,' *Economica*, August 1943, p. 255).

2. The Ricardians

Of all the groups that formed and dissolved during the period under survey, the Ricardian circle alone deserves separate treatment. The brilliance of its central figure, the international prestige it enjoyed for a time, its prominence in public debate, its achievements and failures—all this and more can be adduced in justification of the attempt to make readers visualize it as clearly as possible. Moreover, the group was a genuine school in our sense: there was one master, one doctrine, personal coherence; there was a core; there were zones of influence; there were fringe ends. Let us first look at the core. It really consisted only of Ricardo himself, James Mill, and McCulloch. But we add West and De Quincey. For reasons to be explained later, we do not add J. S. Mill. A fortiori, we do not add Fawcett or Cairnes.

> David Ricardo (1772-1823) entered upon a business career at the age of fourteen (he was first a broker, then a jobber and operator on the stock exchange, always a man of the money market) and made a considerable fortune. This is relevant for us because it means (1) that, though he came from a cultured home, he was all but uneducated in the scholastic sense; (2) that, since such a career is absorbing, only the dregs of his intellect and energy were available for analytic work until 1814 when he retired at forty-two. Nevertheless, he had done the bulk of his analytic work by then, as far as the workshop of his mind (not publication) is concerned. This is a striking proof of his splendid powers, but also the reason why his work, lacking as it did the benefit of full concentration during the third decade of life, which is of decisive importance in a thinker's career, never penetrated down to the deepest depths, besides remaining badly finished in a formal and technical sense: we have before us the record of a wrestler who fought his matches with his right hand tied behind his back. After this, the reader will not suspect me of inadequate admiration for the man when he reads some of my comments upon the work. I shall go further. There is point in defending a figure of which we are justly proud against certain aspersions that are completely unfounded. Some writers have not been ashamed to suggest that his pecuniary interest—as a 'bear'—determined the part he took in the controversies of his time on currency policy. I reply that Ricardo was able enough to make money on rising as well as on falling markets; and I repeat, in addition, that such writers do not seem to realize what it is they are really saying when resorting to such 'explanations,' since the only schemes of motivation that are open to their direct observation are their own. With less indecency, others have interpreted Ricardo as a representative of the 'moneyed interest' and as inspired by a 'hatred' of the landowning class. This, besides being irrelevant for the scientific contents of his writings, is of course sheer nonsense and only proves, if anything, the inability of these interpreters to understand a piece of analytic work. If I cared to waste space, I could prove this inability in each individual case.[1]

---

[1] There is more excuse for the indictment that Ricardo was indifferent to the interests of labor. For though nothing can be farther from the truth, in his almost unbelievable carelessness of formulation he used, on two or three occasions, turns of phrase that seem to support this indictment. Ricardo was constantly complaining of being misunderstood (in this respect in a letter to J. B. Say) and not without justice. In part, however, he had only himself to blame. But, in this so-called indifference, there was

Some day, perhaps, we may see completion of Professor Sraffa's comprehensive edition of Ricardo's works, which we have been eagerly awaiting these twenty years [the first five vols. had appeared by April 1952. Ed.]. Meanwhile, there is McCulloch's edition of the *Collected Works* (1st ed., 1846) prefaced by a memoir of Ricardo. At the moment, since we reserve publications on money for the last chapter of this Part, we are concerned only with Ricardo's *Essay on the Influence of a Low Price of Corn on the Profits of Stock* (1815) and his *Principles of Political Economy and Taxation* (1817; 3rd ed., the one to use, 1821; the reader will presumably resort to E. C. K. Gonner's edition, 1882, last printing, 1929). Any thorough study should be supplemented by perusal of his letters to Say, Malthus, Hutches Trower, and McCulloch (for editions, see article on Ricardo by J. H. Hollander in the *Encyclopaedia of the Social Sciences*, which gives a brief but correct sketch and appraisal of Ricardo's work) and by his *Notes on Malthus' Principles* (ed. J. H. Hollander and T. E. Gregory, 1928; see review by E. S. Mason, 'Ricardo's Notes on Malthus,' *Quarterly Journal of Economics*, August 1928). Of all general interpretations, the most important are: K. Marx in *Theorien über den Mehrwert*; J. H. Hollander, *David Ricardo* (1910); and K. Diehl, *Sozialwissenschaftliche Erläuterungen zu David Ricardos Grundgesetzen* (2nd ed., 1905). Still more instructive for our purposes are E. Cannan's comments in his *Theories of Production and Distribution* (3rd ed., 1917). The literature on Ricardo is immense, especially if we count in, as we should, all the references to him in theoretical works such as Böhm-Bawerk's or Taussig's. I wish, however, to single out two relatively recent studies by excellent theorists that illustrate the extent of the range within which critics of the highest competence may differ as regards the nature and value of Ricardo's performance: Professor F. H. Knight's article on the 'Ricardian Theory of Production and Distribution' in the *Canadian Journal of Economics and Political Science*, vol. I (February 1935), and Dr. V. Edelberg's article, 'The Ricardian Theory of Profits' in *Economica*, vol. XIII (1933).

The discussion above goes some way toward explaining the character of Ricardo's work. In utmost brevity, I shall add the following comments, if only to give the reader some points to reflect upon. Ricardo is usually described as a utilitarian, but he was not one. This is not because of his having had another philosophy but because that busy and positive mind had no philosophy at all. He was on good terms, mainly through James Mill, with the philosophical radicals. Presumably, he often expressed assent to utilitarian tenets. Historians are apt to exaggerate the importance of such things. But they do not mean much. Similarly, he had not an inadequate sociology, but none at all: there were certain economic problems that fascinated his powerful intellect but the socio-

---

also an element of virtue: he was above the unctuous phrases that cost so little and yield such ample returns.

logical framework he took for granted—no matter of reproach this, but simply a matter of division of labor. Given its nature, his theory would not have been improved by being caparisoned sociologically; the critic who misses institutional disquisitions has simply called at the wrong address. But of course this applies only to his theory as theory, it does not apply to his recommendations. In these we do miss insight into the motive powers of the social process and, in addition, historical sense.[2]

Two other points, however, bear directly upon Ricardo's theory as theory. First, Marx's contrary view notwithstanding, Ricardo's was not the mind that, like Thünen's, works from the clay. His method of work was essentially to take hold of the problems that the day presented to him, and to attack them by means of tools that he derived by criticism. The one is obvious at first sight from all his writings except the *Principles* (where it is only less obvious). The other is obvious from the *Principles*. Even if we did not know that Ricardo's thought was inspired by the *Wealth of Nations*, which he took up in 1799 when boring himself at a health resort, we could not help seeing that the argument of the *Principles* starts with a criticism of A. Smith, which really runs through the whole book. With a high degree of confidence, we may reconstruct the development of his thought so far as it was not determined by his interest—analytic and practical—in current events: he studied the *Wealth*; he was shocked at what seemed to him to be a logical muddle; he set about straightening out this muddle; and the *Principles* was the ultimate result of this work of creative criticism. Let us make a note of this: Ricardo's theoretical structure represents a particular way of recoining the *Wealth*; Malthus' theoretical structure represents another way of doing this. As a corollary, I venture to state that Ricardo owed very little to any other writer, though his later study of Say and Malthus and his discussions with both and with James Mill no doubt served to clarify his ideas—of this more in a moment. Second, Ricardo's was not the mind that is primarily interested in either fundamentals or wide generalizations. The comprehensive vision of the universal interdependence of all the elements of the economic system that haunted Thünen probably never cost Ricardo as much as an hour's sleep. His interest was in the clear-cut result of direct, practical significance. In order to get this he cut that general system to pieces, bundled up as large parts of it as possible, and put them in cold storage—so that as many things as possible should be frozen and 'given.' He then piled one simplifying assumption upon another until, having really settled everything by these assumptions, he was left with only a few aggregative variables between which, given these assumptions, he set up simple one-way relations so that, in the end, the desired results emerged almost as tautologies. For example, a famous Ricardian theory is that profits 'depend upon' the price of wheat. And under his implicit assumptions and in the particular sense in which the terms of the proposition are to be understood, this is not only true, but undeniably, in fact trivially, so. Profits could not possibly depend upon anything else, since everything else is 'given,' that is, frozen. It is an excellent theory that can never be refuted and lacks nothing save sense.[3] The habit of applying results of this character to the solution of practical problems we shall call the Ricardian Vice.

---

[2] I do not think that Ricardo ever did much historical reading. But this is not what I mean. The trouble with him is akin to the trouble I have, in this respect, with my American students, who have plenty of historical material pushed down their throats. But it is to no purpose. They lack the historical *sense* that no amount of factual study can give. This is why it is so much easier to make theorists of them than economists.

Presently, we shall try to size up the success of the school. Now we want to define the personal success of Ricardo and to see how he succeeded in forming that school. The first step is easy: no doubt it is possible that, with the public as well as with his fellow economists, his reputation was made by his writings on the great economic issues of his time—in the first instance, by his writings on monetary policy, in the second instance, by his writings on free trade. In all the questions he touched, he was on the side that would have won out anyhow, but to the victory of which he contributed usable argument, earning corresponding applause. Though others did the same, his advocacy was more brilliant, more arresting, than was theirs: there is no superfluous sentence in his pages; no qualification, *however necessary*, weakens his argument; and there is just enough genuine analysis about it to convince practically and, at the same time, *to satisfy high intellectual standards* but not enough to deter. His polemical talent, which combined to an altogether unusual degree readiness, force, and genuine politeness, did the rest. People took to his theory because they agreed with his recommendations. He became the center of a circle that looked to him for guidance and in turn defended his opinions. It is neither his advocacy of winning policies per se, nor his theory per se, that, to this day, makes of him, in the eyes of some, the first economist of all times, but a felicitous combination of both.[4]

But what about his contribution to scientific economics? By far the most important one was, I think, the priceless gift of leadership. He refreshed and irritated. In either case, he shook up. The fruits of his reasoning intrigued all the people who did not see the mechanics I have tried to characterize above. His teaching, in its middle and higher layers, established itself as the new thing, compared with which everything else was inferior, obsolete, stale. Very quickly his circle developed the attitude—so amusing but also, alas!, so melancholy to behold—of children who have been presented with a new toy. They thought the world of it. To them it was of incalculable value that only he could fail to appreciate who was too stupid to rise to Ricardian heights. And all this meant controversy, impulse, new zest, new life, and these constitute valuable contributions in themselves.[5] But there was something else. Economic theory is not a stock of political recipes but, to use Mrs. Joan Robinson's felicitous phrase, a box of analytic tools. And these tools are not a heap of disconnected elements but form an engine. This engine grinds out results, within wide limits, no matter what the concrete problem is that is fed into it. It works the same way, formally, whether the problem is the effect of a tax or of a wage policy, or of a piece of regulation, or of protection and what not. Hence the engine, within those limits, may be constructed once for all to stand ready for use whenever needed for an indefinite variety of purposes. This has always been felt instinctively. Cantillon and the physiocrats brought the idea out into the open. But nobody before Ricardo grasped it as vigorously as he did. In the first two chapters of the *Principles*, he undertook to build such a general-purpose engine. This spelled decisive advance. But, of course, if a defective engine meets with success, that advance may easily prove to be a detour. And let me state at once: *a detour Ricardian analysis was.*

---

[3] Speaking of Lord Keynes's theory, Professor Leontief has called this procedure Implicit Reasoning. The similarity between the aims and methods of those two eminent men, Keynes and Ricardo, is indeed striking, though it will not impress those who look primarily for the advice a writer tenders. Of course, there is a world between Keynes and Ricardo in this respect, and Keynes's views on economic policy bear much more resemblance to Malthus'. But I am speaking of Ricardo's and Keynes's methods of securing the clear-cut result. On this point they were brothers in the spirit.

[4] The reader is invited to observe this additional affinity between him and Lord Keynes. Every word in the paragraph above might be written with reference to the latter.

Construction of such an engine of analysis entailed the consequence that the individual elements that make up general economics were welded together into a systematic unit as they never had been before. However unsystematic Ricardo's *Principles* is in form, it is a systematic performance of the first order in substance. Among those elements themselves there is none for which priority of publication could be ascribed to Ricardo with certainty. Above I have expressed myself to the effect that Ricardo, though he owed much to A. Smith, owed very little to other authors.[6] I believe, in fact, that his subjective originality was of a high order. Moreover he was frank and generous in acknowledgments: though I have criticized A. Smith and shall criticize A. Marshall for inadequate acknowledgment, I do not think that any such criticism should be made with reference to Ricardo.[7] But objectively, all the ideas of the *Principles* are individually met with before, and we cannot attribute more than effective synthesis to Ricardo, unless (1) we decide to say that, after having gone out with A. Smith to hunt beaver and deer, Ricardo did twist Smith's suggestion into a labor theory of value that was his own, and (2) we decide to disallow Torrens' claim, mentioned in footnote 7.

---

[5] See preceding footnote.

[6] Barton may be an exception (see below, ch. 6, sec. 6h). Ricardo's preface mentions Turgot, Steuart, Smith, Say, Sismondi 'and others' (besides Malthus and West's essay, see next footnote). But only Smith's influence is of first importance. Say influenced Ricardian teaching only in one point (Law of Markets). I find no trace of any influence of Turgot, Steuart, or Sismondi.

[7] Claims were raised against him, however, especially in three instances. West complained with some bitterness that Ricardo failed to recognize his priority as regards the theory of the falling rate of profits. Ricardo said in the original preface to the *Principles* that 'in 1815, Mr. Malthus . . . and a Fellow of University College, Oxford [West] presented to the world . . . the true doctrine of rent. . .' It is true that he failed to make a similar acknowledgment about profits. But it may be replied that this matter is covered by the acknowledgment of West's priority as to the theory of rent. Torrens was inclined, though mildly, to vindicate a title to priority as regards the theorem of comparative costs. He may have been right. But even if he was, there is a difference

A Reader's Guide is easy to give but, owing to Ricardo's lack of system (in the formal sense), much less easy to follow. The analytic engine is displayed in the first two chapters of the *Principles*. Every line is important, and sections 4 and 5 of the first chapter are as difficult to absorb as is anything the reader may run up against in economic literature. Chapter 31, 'On Machinery' added in the third edition, to which alone this guide refers, complements those fundamentals in one important point. All the rest is really only development (chs. 3-6), application (chs. 8-18 and 29, all on taxation), defense and criticism (chs. 20, 21, 24, 26, 30, 32), but, unfortunately, contains so many *obiter dicta* on fundamentals as to make it very hazardous to skip. For example, Chapter 27, 'On Currency and Banks,' which together with Chapter 28 deals with matters that the student of Ricardo's general theory might feel inclined to neglect, contains passages that shed much-needed light on Ricardo's handling of the theorem that marginal cost equals price, and on the sense in which he was in full possession of it. Foreign trade is dealt with in the famous Chapter 7, which is also really a supplement to the fundamental ones (and is itself supplemented by chs. 22, 23, and 25). Chapter 19 (and, in a sense, also 21) pledged Ricardo's allegiance to Say's law.

So brilliant a light will attract moths—there are a certain number of obscure Ricardian writers. Moreover many people, noneconomists included, will profess themselves votaries of the light even though they have but a dim perception of it—just as today there are many Keynesians and Marxians who have never read a line of Keynes or Marx. In addition, *some* of the independents, even a few dissenters such as Torrens, will still profess decent respect for the eminent fellow economist from whom they dissent, and be quite ready to use phrases and propositions of his wherever they feel they can. Finally, economists of later generations—conspicuous instances were J. S. Mill and A. Marshall—may pay homage to a great name of the past in such a way as to hide from themselves and others the full extent of the gulf that separates them from him. All this is apt to mislead the retrospective glance and to make the influence of Ricardo and his school look greater than it actually was. In the interest of a true picture of the history of economic analysis, it is necessary to reduce this influence to its proper proportions.[8]

---

between an author's behavior in such matters in a hasty sketch such as the *Principles*—no contradiction to the statement about the systematic nature of Ricardo's performance!—and an author's behavior in such matters in fully matured works that had been elaborated with infinite care such as A. Smith's *Wealth* and A. Marshall's *Principles*. The third claimant was J. Rooke, *Claim to the Original Publication of certain new Principles* . . . (1825), unearthed by Professor Seligman. So far as I can see, he has no case at all.

[8] It cannot be repeated too often that for any purpose other than that of a history of *analysis* there would be no need for any such operation, and that the influence we mean to appraise is influence upon scientific economics only.

We have already seen that the core of the school consisted of only four men besides Ricardo himself. By this I mean that James Mill, McCulloch, and De Quincey were the only unconditional adherents and militant supporters of Ricardo's teaching who gained sufficient reputation for their names to survive. West[9]—partly because he went to India—stood apart. He was, and felt himself to be, no member of any school but the peer of Ricardo and the independent discoverer of the essentials of Ricardian doctrine. His evident resentment against Ricardo was probably unjustified. But his regret at being ousted from what he conceived to be his place, by the latter's superior force and brilliance, was not. For the *Essay* contains in fact not only a formulation of the 'Ricardian' theory of rent but also the application of the law of diminishing returns to a theory of profit, hence the pivot of the Ricardian system. Therefore, though we have no choice but to include him in the 'Ricardian' school, we shall temper this injustice by speaking occasionally of West-Ricardian doctrines.

James Mill must certainly be recognized as a man of light and leading, irrespective of what we may think of the value of the light he shed and of the leads he gave.[10] McCulloch[11] has been so roughly handled by Marx and others,

---

[9] Sir Edward West (1782-1828), one of the foremost scientific economists of the age, has never received his due. His *Essay on the Application of Capital to Land* . . . (1815, reprinted in Professor Hollander's series of economic tracts, 1903) is much more than a mere statement of the law of diminishing returns, which is how it is usually described in the history of economics. His second book, *Price of Corn and Wages of Labour* . . . (1826), is marked by the same independence of thought.

[10] We have met James Mill (1773-1836) twice already, both times in strategic positions: as the author of the *Analysis of the Phenomena of the Human Mind* (1829) and as the exponent of the official Benthamite doctrine on government. We have to add his monumental, and indeed path-breaking, *History of British India* (1817), which posthumously grew into ten volumes and was the cornerstone of his reputation with the general public, and his two economics books (a third, the earliest one, I do not know), viz. *Commerce Defended* (1808) and *Elements of Political Economy* (1821; 3rd ed., the one to be used, 1826). The author in the preface described the latter as a 'schoolbook' and as devoid of originality (not quite true, though the original points were not all improvements. As has been recognized, e.g. by Marx, the book represents an effort that was by no means contemptible). The standard biography by A. Bain (1882) fails to do justice to the economics of James Mill and also to solve the enigma of the man—that intellectual machine that did not know how not to work.

[11] John Ramsay McCulloch (1789-1864) was a journalist, academic teacher, and civil servant and, though the most unphilosophical of men, may be counted in with the philosophical radicals. Neglecting for the moment his factual work, I shall mention only his *Principles of Political Economy* (1825; 5th ed., 1864); his *Literature of Political Economy* (1845), a fairly comprehensive annotated catalogue and immensely useful as such (the comments on each author, written from the standpoint of a naïve and unquestioning faith in Ricardian doctrine, are a revelation for anyone who wishes to grasp the spirit of the Ricardian school); and the *Essay on the Circumstances which Determine the Rate of Wages* (1826), his most ambitious effort in economic theory. Both his letters to Ricardo and Ricardo's letters to him have been published, in 1931

Böhm-Bawerk among them, that it seems right to emphasize his merits rather than the fact that his ability, though of a most useful kind, was not of a high order. His factual work, an important achievement, will be mentioned later. His zest for social reform—into which entered an element that spells some analytic merit: he was a leading exponent of the 'wage-fund theory' but realized that this theory does not prove the futility of trade-union wage policy—should recommend him to modern critics. Moreover, he rose to be one of the best-known figures of the profession in his day, and succeeded in keeping the flag of Ricardianism flying when practically all other economists had deserted it: and this is something. Finally, he wrote the textbook that was the most successful general treatise England produced in the first four decades of the nineteenth century, and this, all the shortcomings notwithstanding, is not negligible either;[12] the book was more directly influential with the public than was Ricardo's and really created what we might call lower-level Ricardianism. De Quincey, of Opium Eater fame, is a different case. His delight in refined logic makes him the very antipode of the rough and ready McCulloch. But he touched economics peripherically only. And his contribution, though interesting, was sterile.[13]

None of the three added anything substantial, and the touches they did

---

and 1895 respectively, by Professor J. H. Hollander. They are one of the most important sources for the study of that time's methods of theoretical reasoning.

[12] Speaking of texts, we should not pass by Mrs. Jane Marcet's *Conversations on Political Economy* (1816), which enjoyed a great success (7th ed., 1839). James Mill's was an elementary, but not an easy, text on pure theory. McCulloch's was the saleable stuff for the college course in general economics. Mrs. Marcet's was economics for what we should call high-school girls. The reader should really look at it and note two interesting points about it. The first is the date: the book appeared *before* Ricardo's *Principles* and, though not orthodox Ricardianism in every particular and though lacking Ricardian rigor, yet presents many of the most important tenets of the Ricardian school. This is significant, and greatly enhances the interest of the performance, at which it is quite out of place to sneer. Second, if nevertheless so many later economists did sneer at it, this was due not only to male prejudice but also to the nature of the publication: not for a moment did Mrs. Marcet doubt not only that the definitive truth about economics and economic policy had been discovered at last but also that this truth was so delightfully simple as to be capable of being taught to every school girl. This frame of mind was then common and is highly characteristic of that age—exactly as a similar frame of mind is common among modern Keynesians and not less characteristic of our own age.

[13] 'Dialogues of Three Templars on Political Economy,' *London Magazine*, April 1824—let us bow to the editor who published such material and to the reading public that did not thereupon discontinue subscription—and *Logic of Political Economy* (1844). The book survives, I think, only through J. S. Mill's generous quotations from it. I cannot see in it anything original. The concept of Difficulty of Attainment is Ricardo's, and had already been formulated by the latter in a much more suggestive way ('the real value of a commodity is regulated . . . by the real difficulties encountered by that producer who is least favoured,' *Principles*, ch. 27).

add—James Mill and McCulloch especially—were mostly of doubtful value.[14] They did not even succeed in summing up Ricardo correctly or in conveying an idea of the wealth of suggestions to be found in the latter's *Principles*. What they did convey was a superficialized message that wilted in their hands and became stale and unproductive practically at once. It was not their fault that Ricardo's system failed from the first to gain the assent of a majority of English economists—and not only, as the Ricardians tried hard to believe, of the dunces and laggards. This was owing to its inherent weaknesses. Nor was it their fault that the system was not made for a long career. But it was their fault that defeat came so quickly. Ricardo died in 1823. In 1825, Bailey launched his attack that should have been decisive on the merits of the case. Actually it was not, for schools are not destroyed so easily. But the decay of the Ricardian school must have become patent shortly after, for in a pamphlet published in 1831 we read that 'there are some Ricardians still remaining.'[15] In any case, it is clear that Ricardianism was then no longer a living force. The prevailing impression to the contrary can be easily accounted for. There were the henchmen who continued to stand by their guns and to teach exploded doctrine as if nothing had happened. There was the lag of public opinion, which is as slow to realize the passing of an obsolete doctrine as it is to realize the birth of a new one. And there was something else that is still more important and will explain why few if any historians will agree with me: there was Ricardo's *personal* prestige, the great name that survived the work. As has been pointed out already, Ricardo, though not particularly fortunate as regards his immediate followers, has been all the more fortunate in another respect. J. S. Mill emphasized his early Ricardianism throughout and neither realized himself nor made it clear to his readers how far he had actually drifted away from it by the time he wrote his *Principles*. And, to a lesser extent, even Marshall and Edgeworth did the same thing. Moreover, Ricardo's fame does not rest on his theoretical structure alone. On the one hand, there were his contributions to the theory of money and monetary policy and his theory of international trade. On the other hand, certain individual elements of that structure proved more durable than did the whole. The most important instance is his theory of rent, in spite of the fact that logically it should have been scrapped with the rest.

Foreign zones of influence present, in part, a different picture.[16] Marx and Rodbertus did much to keep Ricardian thought alive. Partly by virtue of their influence, partly because of the weakness of domestic competition—and, later on, also because of the prevalent dislike for the Austrian theory—Ricardo remained to the end of the century *the* great theorist for most of those German economists who had any theoretical ambitions at all: the names of Wagner,

---

[14] Ricardo is, e.g., not chargeable with either James Mill's or McCulloch's theories of interest or with the whole of the latter's wage-fund theory.

[15] This phrase from C. F. Cotterill, *Examination of the Doctrine of Value . . .* (1831), is quoted by Professor Seligman (op. cit. sec. 3), to whom I owe this reference.

[16] For influence of Marx and Rodbertus, see below, sec. 5.

Dietzel, and Diehl are illustrative examples. For the period under discussion, but not beyond it, an analogous statement holds—or almost holds—for Italian economics. There are strong traces of Ricardo's influence in the writings of Ferrara and in the textbooks. Rossi affords another instance if we count him as an Italian, but almost the only one of importance if we call him a French economist. France, following her own tradition, resisted Ricardian influence more than did any other country. In the United States, McCulloch's textbook conquered a large amount of ground—tying with Say's for first place in teaching. And there was also Ricardian influence on a higher level far into the next period—of front-rank names, Taussig's is an illustration.

What I meant by 'fringe ends' of the Ricardian school may be best illustrated by indicating the most important group that comes within the meaning of this term, the so-called Ricardian socialists. Of course, Marx was the greatest of Ricardian socialists, but the group is usually defined more narrowly; namely, so as to comprise a number of writers who, mainly in the 1820's and 1830's, argued the case of the working class on the proposition that labor is the only factor of production. Though this proposition harks back to Locke and Smith and not to Ricardo, it is likely that the Ricardian theory of value did encourage these socialist writers and also offered suggestions to them. Since the writings of this group, which of course is entitled to a great place in the history of socialist thought, offer but little that is relevant to a history of economic analysis, we shall confine ourselves to mentioning the two names that seem to be, for us, more important than others. William Thompson's *Inquiry into the Principles of the Distribution of Wealth . . .* (1824) is a fair example, on its higher level, of the group's argument, of its tempered equalitarianism, and of its habit of considering ideals of distribution, irrespective of the repercussions that realization of these ideals might have on production. Benthamite influence is strongly marked. Thomas Hodgskin's *Labour Defended against the Claims of Capital . . .* (1825) and *Popular Political Economy* (1827) display at least traces of genuinely analytic intention.[17] It should be observed that as soon as an author combines the idea that labor is the only source of wealth and that the values of all commodities can be represented in terms of labor hours with the idea that labor itself is a commodity, he is inevitably drawn to the conclusion that the market mechanism robs the workman of the difference between the labor value of 'his' product and the labor value of the amount of work invested in that product. This, barring details, is the Marxist theory of exploitation. Accordingly, several Ricardian socialists have been called forerunners of Marx. The phrase 'forerunners' may mean much or little, and if it is not made to mean too much, that statement may be allowed to pass muster, though I cannot find any instance (not even in Thompson and Hodgskin) that would amount to full anticipation of all that Marx's theory of exploitation means within his system. But the charge of plagiarism is unfounded, if for no other reason, because that combination of ideas is bound to occur to any student of Ricardo who develops his teaching in the direction in which Marx wished to develop it. It is significant that this charge, though often repeated by economists, was in the first instance raised by a writer who was not an economist himself, Anton Menger (1841-1906; brother of the economist), to whose *Recht auf den vollen Arbeitsertrag* (1886; the English trans., *Right to the Whole Produce of Labour*, 1899, has an important introduction by H. S. Foxwell) the reader is for the rest referred. The theory of the more important writers of the group stands out better in Esther Lowenthal, *The Ricardian Socialists*, 1911.

---

[17] J. F. Bray's *Labour's Wrongs and Labour's Remedy* (1839) has been reprinted by the London School (1931) and has thereby been transformed from the least into the most accessible of these writings. This is my only reason for mentioning it. See M. F Jolliffe, 'Fresh Light on John Francis Bray,' in *Economic History, A Supplement of the Economic Journal,* February 1939.

3. MALTHUS, SENIOR, AND SOME OF THOSE WHO ALSO RAN

In spite of our objections to speaking of national schools, we shall review by countries the rest of the men still to be mentioned. For England, since we have noticed Longfield already and since we reserve J. S. Mill and Cairnes for the next chapter—and Jevons, of course to the next period—we are left primarily with Malthus and Senior. But we must not confine ourselves to the performances that are known to history and leave all others in the shade. This would create a wrong picture. For historical performances are rarely like erratic blocks in a plain. They are more like peaks that rise from clusters of smaller eminences. In other words, a science develops by small accretions that create a common fund of ideas from which, by chance as well as by merit, emerge the works that enter the hall of fame. Therefore we must add at least a few of those writers who, though they failed to achieve historic fame, yet did important work and exerted an influence upon developments in analysis that are anonymous but not negligible. In taking some account of them, we shall also establish our proposition that the West-Ricardo school was never dominant in English economics.[1]

(a) *Malthus.*[2] Marx poured on him vitriolic wrath. Keynes glorified him.

---

[1] Let me repeat that writers whose performance was wholly in the fields of money, banking, and cycles will be dealt with separately.

[2] Thomas Robert Malthus (1766-1834) was a clergyman and a professor of history and political economy at the East India College at Haileybury. As we already know he leapt into fame, from complete obscurity, in 1798 when he published his *Essay on the Principle of Population* (2nd ed. 1803; 3rd 1806; 6th 1826). Of his numerous other writings (neglecting those on money), the following are, for us, the most important: (1) . . . *High Price of Provisions* . . . (1800); (2) *Letter to Samuel Whitbread on* . . . *the Poor Laws* (1807); (3) *Observations on the Corn Laws* (1814); (4) *Inquiry into the Nature and Progress of Rent* (1815); (5) *Grounds of an Opinion on the Policy of Re-*

Both the vituperation and the eulogy are readily seen to be due to prejudice. Marx—or the laicist bourgeois radical in him—hated nothing so much as the clerical cloth. Moreover, though he never gave any credit to the men who stood for free trade in food, he had nothing but withering scorn for those who did not. These were just hirelings of the landed interest for Marx and, of course, for his obedient followers. This way of disposing of Malthus' contribution is no better than other people's method of disposing of Ricardo's on the grounds that he was a Jew and 'for the money interest.' But Keynes's partiality for Malthus, though morally admirable—for those are few who extol a forerunner and Keynes believed Malthus to have been a forerunner of his—went to lengths that are not much less unreasonable than was Marx's hatred.[3] And right from the publication of the *Essay on Population* to this day, Malthus has had the good fortune—for this *is* good fortune—to be the subject of equally unreasonable, contradictory appraisals. He was a benefactor of humanity. He was a fiend. He was a profound thinker. He was a dunce.

The man whose work stirred people's minds so as to elicit such passionate appraisals was *ipso facto* no mediocrity. The man who realized that some economic problems are like the problems 'de maximis et minimis in fluxions' [calculus] was no dunce. His case illustrates the difference between ability and brilliance. Soundness would be the word for him if it were not for a failing that he shared with many—most?—economists. He had a few pet ideas, which he was bent on applying to practical problems. And when he did so, his usual common sense was apt to turn out nonsense.[4] Moreover he was not a good controversialist.

---

stricting the Importation of Foreign Corn (1815); (6) *Principles of Political Economy* (1820; i.e. one year after Sismondi's *Principles*); (7) *Measure of Value* (1823); and (8) *Definitions in Political Economy* . . . (1827)—(4) and (6) being in turn the most important of these. See especially J. Bonar, *Malthus and His Work* (1885, 2nd ed., 1924; the standard work on Malthus, a *little* unsatisfactory with respect to pure theory), and Lord Keynes's charming essay on Malthus in *Essays in Biography* (1933), which the reader is sure to enjoy and which makes it superfluous for me to say anything concerning the subject of 'backgrounds and formative influences.' Let me notice briefly the three accusations of plagiarism that have been leveled at Malthus by Marx. The first we know already: it refers to Malthus' forerunners, Townsend especially, in the theory of population. The second concerns his theory of rent (diminishing returns). Marx was quite sure that Malthus had plagiarized Anderson but failed to produce any substantial reasons why: the type of argument that makes Malthus a plagiarist in this case would, if admissible, also make a plagiarist of Marx. The third concerns the theory of gluts: Malthus is supposed to have plagiarized Sismondi. Apart from the considerable differences between the theories of the two, there is no reason why Malthus could not have arrived at the position he took in the *Principles* from ideas that were present in his mind *at least* as far back as 1814 (see Keynes, op. cit. p. 141).

[3] A passage in the essay referred to above actually reads as if Lord Keynes attributed to Malthus the 'beginning of systematic economic thinking' (p. 125).

[4] The outstanding instance of this is his *Letter to Samuel Whitbread* (see last footnote but one). In this piece he argued against a housing program of Whitbread's (cottages to be built by the parish authorities) on the ground that this would encourage

For the public and also for a majority of the profession, Malthus was and is primarily the Malthus of the *Essay on Population*. His second title to fame, his contribution to monetary analysis, has almost escaped the attention of historians. His third title, the one that has brought his name to the fore in our own time, is his theory of saving and investment or his theory of 'general gluts.' [5] For the moment, we are concerned with a fourth title to fame only, namely, as the author of a system of economic theory that recoined the theory of the *Wealth of Nations* in a manner that was the alternative to Ricardo's recoinage. Deferring consideration of his theory of rent and of other points of comparative detail, we must now make sure of this point.

We have seen that Ricardo's work, so far as general theory is concerned, started from the *Wealth of Nations* and recoined the latter's theoretical contents by a method that centered in the concept of value. Exactly the same thing is evidently true of the work of Malthus as presented in his *Principles*. Except for his theory of saving and investment, which on the face of it seems to be Malthus' own,[6] all the elements that enter into the analytic apparatus of that work, and even its terminological arrangements, point to the First Book of the *Wealth of Nations*. Only, whereas Ricardo recoined the doctrine of the *Wealth* by means of the labor-quantity theory of value, Malthus recoined it by means of the theory of value that A. Smith actually used, namely, the theory of supply and demand,[7] also following A. Smith's example in choosing labor as a unit of value (*numéraire*). Therefore, Malthus adopted the line that won out ultimately and pointed much more directly to the Marshallian system than did Ricardo's, notwithstanding the fact that it was with the latter and not with the former that Marshall endeavored to keep in contact.[8]

---

improvident marriages. Even Keynes had nothing to say for this. He treated this just as an incident and condoned it good-humoredly. This means, however, that he failed to see its implications concerning the recommendations that emanate even from front rank economists. Is the public really to be blamed for not taking them seriously?

[5] For the discussion of these three phases of Malthus, see above, ch. 1 and below, chs. 6 and 7.

[6] Unless we choose to hunt for forerunners far back in the eighteenth century, the only author that might qualify as a forerunner in this respect is Lauderdale. Sismondi is not a forerunner but a competitor though, so far as his teaching coincides with Malthus', he holds priority as to publication. [J. A. S. had penciled a note—'Quesnay?']

[7] We shall see later that the labor quantity and the supply-and-demand theories should not, in logic, be put into opposition. But both Ricardo and Malthus took them mistakenly for alternatives. I adopt this view for the moment, because they do serve nevertheless to characterize the two different apparatus of analysis.

[8] This tendency of Marshall's, which runs throughout his *Principles*, has done much to obscure the actual situation. Here I shall only state by anticipation that, in spite of all that Marshall said, it is the supply-and-demand apparatus which dominates the analysis of his Fifth Book. There is, however, another confusion to which I want to draw attention at once. Analysis that works by means of supply and demand has no difficulty in covering short-run phenomena as well as long-run phenomena. It has been repeated over and over again that Malthus, unlike Ricardo, was primarily interested in short-run phenomena. To some extent this is true. But it has been assumed too readily

This also holds with respect to another difference between the two. We have seen that Ricardo's analytic apparatus is geared to the problem of distribution—to the explanation of relative shares. Malthus, again returning to A. Smith and again anticipating A. Marshall, geared his apparatus to the analysis of the whole economic process. Hence he treated total output (Marshall's 'national dividend'), not, like Ricardo, as a datum, but as the chief variable to be explained.[9] Therefore, Malthus should indeed, though for a reason that does not coincide with that which induced Lord Keynes to arrive at a similar result,[10] stand in the history of analysis not only as the author of a valid alternative to Ricardo's theory but as the sponsor (or rather as one of the sponsors) of the victorious one. This is much. At the same time, it is all. It is perfectly compatible with recognition of these facts that much less ingenuity went into Malthus' than into Ricardo's analytic schema, and that the former was throughout in the most unenviable position an economist can be in, namely, in the position of having to defend plain sense against another man's futile but clever pirouettes.

(b) *Archbishop Whately and Professor Senior.* Next, we look at Senior and the man who had been his tutor, Whately. The latter's [11] importance for us is as great as it is elusive. He was not profound or very learned. He was not orig-

---

that it was *because* of this interest in short run phenomena that he selected supply and demand as the pivot of price analysis. This is not true. As should be clear from the text, his difference with Ricardo on the subject of value was much more fundamental than that—which Ricardo failed to realize. [It is possible that J. A. S. intended to eliminate this footnote. There was a faint line through it.]

[9] Incidentally, this different point of view involved a different conceptualization and naturally led him to find fault with Ricardo's. This he made particularly clear in his *Definitions*. Once more he expressed himself inadequately. He reproached Ricardo with a use of terms that was both unusual and inconsistent, as if this were all. But, just as before, there was something more fundamental at stake than terminology. What he should have objected to this time was Ricardo's analytic intention of which the terminology was but the consequence. This intention was open to objection on the ground that it neglected the really relevant problems for the sake of propositions that were partly less relevant to the purposes of economic analysis and partly sterile.

[10] For Keynes, the decisive point was Malthus' attitude toward saving. For us, it is his sponsorship of the Smith-Marshall output analysis, which, as these two names suffice to show, is not necessarily bound up with that attitude.

[11] Richard Whately, D.D. (1787-1863), was an Oxford don who became (Anglican) Archbishop of Dublin, where he founded the chair of political economy and rendered innumerable services of the same type. But they do not sum him up or characterize him. Primarily, he was a theologian and a leader of Anglican Church policy and opinion. But this does not sum him up either. Nor does, finally, his extensive activity in the *Sozialpolitik* of his age and country. His *Introductory Lectures on Political Economy* (1831; enlarged ed., only one known to me, 1855) and his *Easy Lessons on Money Matters* (1833) would not suffice to place him high as an economist. More interesting is an appendix to his *Logic*, 'On certain Terms which are peculiarly liable to be used ambiguously in Political Economy' (republished in the Library of Economics Reprint of Senior's *Outline*). There is an instructive life by Miss E. J. Whately (1866) that pictures not only a man but also an environment and an epoch.

inal or even brilliant. But his clear and strong intellect grasped calmly and firmly whatever it did grasp within an unusually wide range of interests. And in his age, country, and world, he was a leader of the formative type, an ideal illustration of what is meant by a key man. He led quietly, without seeming to do so, by the weight of his personality and of his advice which was never more valuable than when it was obvious. For in ecclesiastical politics, as in economics, the obvious is sometimes precisely what people are most reluctant to see. His most important service to economics was, however, that he formed Senior, whose whole approach betrays Whately's influence.

Senior [12] has been treated with comparative neglect by many economists and with uncalled-for scorn by some. In reaction to this, others have made a 'genius' of him, which he assuredly was not, if I understand what this word means. In our picture he will enter a triumvirate with Malthus and Ricardo: he was one of the three Englishmen whose works are the main stepping stones between A. Smith and J. S. Mill. But J. S. Mill had, logician though he was, no eye for Senior's great performance. To the latter's eternal honor—which he may have to share with Whately—it must be recorded, in the first place, that he attempted to unify and present economic theory according to the requirements of the postulational method, that is, as a series of deductions from four induced or empirical postulates, which we shall discuss in Chapter 6. This, even if the result fell considerably short of perfection, makes him indeed the first 'pure' theorist of that period—always excepting Cournot and Thünen, perhaps also Longfield—and suffices by itself to condemn those who refuse to pay their respects to him. In the second place, he adumbrated a much improved theory of value and a much improved theory of capital and interest. In the third place stand various smaller merits, some of which will be mentioned in their proper connection (population, decreasing returns, rent). In the fourth place, his brilliant contributions to the theory of money, to be mentioned in the last chapter of this Part, are, considered as purely intellectual performances, not inferior to Ricardo's. I should put his subjective originality quite as high as Ricardo's. Objectively, he had been anticipated, like Ricardo, on most of the individual points he made. Why, then, will so few economists agree with an estimate that puts Senior on a par with Ricardo, and why has his influence been restricted, substantially, to what J. S. Mill took over from him? [13]

---

[12] Nassau William Senior (1790-1864) was a highly educated Oxford man of whose uneventful life, financed mainly by modest independent means, two facts only need be recorded here: he held the Drummond Professorship at Oxford twice (1825-30 and 1847-52); and he worked on several important royal commissions. His work with these commissions amounted to a respectable quantity of factual research and should also clear him from any suspicion of having been a doctrinaire laissez-faire man. Besides his lectures on money, now available in the London School Reprints (1931), only his *Outline of the Science of Political Economy* (1836; Library of Economics Reprint, 1938) is essential for us. We owe to Dr. Marian Bowley an excellent interpretation of Senior's work and of its place in the history of economics (*Nassau Senior and Classical Economics*, 1937), to which I wish to call my readers' attention and which enables me to cut short this note. Differences between her interpretation and mine are few and not important. Her tendency to distance Senior from the 'classic' economists—to whom he belongs according to the terminology adopted in this book—creates, however, some differences that are more apparent than real.

There are three excellent reasons for this that illustrate the difficulty of even as much comparative appraisal of economists as is inevitable, if we are to get a picture of a scientific situation at all. First, even if we are firmly resolved to estimate analytic merit only, we are apt to forget that Ricardo speaks to us from a pedestal, the pedestal of a reputation made in public discussion of political issues. There is no such pedestal under the figure of Senior. He counts as an analytic economist only. His work on problems of policy is buried in bluebooks that hardly anyone reads. His public utterances made no mark and he was a nobody, or almost so, to the general public. Second—and this was entirely the fault of his mental make-up—he was, what is the word? Lazy? By this I do not mean to suggest that he did not do a lot of work, but rather that he lacked the kind of energy that will run purposefully to definite conclusions. Ricardo was the horse that will take hold of the bit, put out its nose, and gallop for what it is worth. Senior was the horse that drops the bit, puts its nose down, and refuses to stretch. His *Outline*, still worse in arrangement than Ricardo's *Principles*, discusses, criticizes, hesitates, swerves. It fails to impress, as the latter does, by ardor. Worse still, Senior's reader gets the impression, nay, he is told in so many words, that all economic analysis amounts to is the search for, and consistent use of, a convenient terminology. Was this Whately's fault? [14] In any case, nothing could be further from the truth and nothing could have been more uninspiring. Other economists—in fact most of them throughout the nineteenth century—used and defended the hunt for the meaning of words as a method of research. But nobody went as far as Senior, who seemed inclined to *solve* all problems of his 'science of political economy' by laying down definitions. We shall have no difficulty in understanding how such a 'method' must have impressed hostile critics. And, third, Senior had a curious talent for 'putting his foot in it.' Even good Homer dozes off occasionally, as an old slogan avers. But Senior dozed off, that is, uttered ineptitudes, rather too frequently. He was careless. And though *able* he was not *clever*. Thus, to quote only the most famous instance, he actually wrote (*Letters on the Factory Act* . . . 1837) a statement to the effect that the profits of cotton mills, assumed to be 10 per cent, would be completely wiped out by a reduction of the working day by one-eleventh because the whole of those profits was produced in the last hour. This could not have happened with Ricardo, though we might put Senior above him in other respects.[15]

---

[13] J. S. Mill's opinion of Senior was even higher than we might infer from his references to him: Mill had his copy of the *Outline* interleaved with sheets on which to note his own comments. These comments, published by Professor von Hayek in *Economica*, vol. XII, August 1945, are of the utmost interest.

[14] With his usual common sense, Whately pointed out (in his *Elements of Logic*) that many of the issues economists quarreled about were purely verbal and that loose use of terms, both a cause and a consequence of loose thinking, was a fertile source of misunderstandings. But he overshot the mark, when he seemed to consider the possession of 'a vocabulary of general terms as precisely defined as the mathematical,' not only as an important desideratum but practically as the only thing needful.

(c) *Some of Those Who Also Ran.* For the reason explained at the beginning of this section, I shall now add a few more names. Other writers would no doubt mention other names, in part at least, but my selection is this: Bailey, Chalmers, Lauderdale, Ramsay, Read, Scrope, and Torrens.[16] Their performances differ widely in nature and are difficult to co-ordinate, though they do round off our picture. However much I wish to avoid cataloguing, I nevertheless present them in alphabetical order.

Bailey,[17] as already mentioned, attacked the Ricardo-Mill-McCulloch analysis on a broad front and with complete success. His *Dissertation*, which said, as far as fundamentals are concerned, practically all that can be said, must rank among the masterpieces of criticism in our field, and it should suffice to secure to its author a place in or near front rank in the history of scientific economics. Nor did his work pass unnoticed. Several writers, Read among them, acknowledged indebtedness to him and followed his lead, and it is safe to assume that his influence extended beyond the range of explicit recognition. Nevertheless, historians who to this day fail to give Bailey his due are only accepting the facts of the case as it presented itself at the time. Writing in 1845, McCulloch did not risk provoking laughter when he wrote in his *Literature of Political Economy* that Bailey had not properly appreciated the Ricardian theory and had not 'succeeded in any degree in shaking its foundations,' in the face of the fact that a poll of writers on value from 1826 to 1845 would produce a considerable majority for Bailey. These are the explanations I have to offer. First, in science as in art and especially in politics, there is such a thing as coming too soon; and failure, much more complete than was Bailey's, is the usual result of premature action. Second, Bailey's criticism was indeed constructive and did suggest by implication how the system he attacked could have been replaced by a more satisfactory one; but he did not try to do so, and those who followed in his wake and tried were no match for the shadow of Ricardo. They no doubt undermined his system and thus helped toward J. S. Mill's transformation of it, but they did so by a slow process of attrition rather than by spectacular victory.

---

[15] That Senior arrived at this absurd result after a careful examination of facts, only makes matters worse, as far as his competence in applied theory is concerned. On the other hand, Marx's scathing attack upon Senior's argument in the first volume of *Das Kapital* does not enhance our idea of Marx's competence either. In all the pages of vituperation that he bestowed upon it, he failed to adduce the decisive criticism, which he does not seem to have perceived. He overlooked also another thing, namely, that Senior's argument would have been correct (at least in principle), if Marx's own theory had been. The reasoning of both Senior and Marx may, however, give pause to those who refuse to recognize the advance in analytic technique that has occurred since. And the case also serves to illustrate another point that cannot be impressed upon the reader's mind too often. The essential thing is that both Senior and Marx committed mistakes, revelatory of inadequate technique. These mistakes were mistakes quite irrespective of the cause for which they argued. To note that Senior was 'for' and that Marx was 'against' the mill owners is entirely irrelevant. And to blame the one and to praise the other, according to the side we take ourselves, is childish.

[16] It was Professor Seligman's paper 'On Some Neglected British Economists' (mentioned above), which drew my attention to Read; Dr. R. Opie's paper (in the *Quarterly Journal of Economics*, November 1929) which drew my attention to Scrope, who until then had impressed me only by his contributions to monetary theory and policy; and Marx's *Theorien über den Mehrwert* which drew my attention to Ramsay. Two important names, those of Jenkin and of Jennings, are being transferred to Part IV. Of course, West was quite typically one of those who 'also ran.' But it seemed better to couple him with Ricardo.

[17] Samuel Bailey (1791-1870). The only publication of his that need be mentioned is *A Critical Dissertation on the Nature, Measures and Causes of Value; chiefly in Reference to the Writings of Mr. Ricardo and His Followers* (1825; London School Reprint, 1931). Perhaps I should add his reply to a grossly unfair criticism in the *Westminster Review*, 'Letter to a Political Economist,' 1826. Both in unfairness and lack of understanding of Bailey's points, the Westminster reviewer was however outdone by Marx (*Theorien über den Mehrwert*).

In this process of attrition, Chalmers'[18] influence counted for a good deal, at least in Scotland. As a theorist, he was thoroughly un-Ricardian and followed the line of what we have called Malthus' recoinage of the *Wealth of Nations*. He also followed Malthus in matters of general gluts and oversupply of capital. If it were possible to speak of a Malthusian school *in general theory* (which I doubt), Chalmers would have to figure as its McCulloch—which is, after all, not so left-handed a compliment as it may seem to the reader.

Lord Lauderdale[19] stands somewhat out of line and holds only a secondary position in the history of economics, but one that is fully deserved and independent of the additional recognition that should now be extended to him on account of his argument against debt redemption (*Three Letters to the Duke*

---

[18] The Rev. Thomas Chalmers (1780-1847), whose activities included teaching of moral philosophy and political economy (at St. Andrews) and divinity (at Edinburgh), was a man of many merits. We cannot claim more than a fraction of him for analytic economics. Only two of his works need be mentioned: his *Enquiry into the Extent and Stability of National Resources* (1808), partly incorporated in his *On Political Economy* (1832). The latter is a book of considerable importance, but not easy to appraise. It presents a curious mixture of sound insights and technical shortcomings. And these shortcomings sometimes account for patently untenable results such as the proposition that a loss of foreign markets is almost a matter of indifference to a country—which overlooks the whole of the division-of-labor argument—though it may be interpreted as an overstatement of the true proposition that (after adaptation) the loss of foreign markets need not affect *employment*. We shall have to mention the book again. Chalmers seems to have coined the phrase, though of course not the concept, 'margin of cultivation,' and is the author of the argument, much appreciated by J. S. Mill, that explains why ravages of wars are in general quickly repaired.

[19] James Maitland, eighth Earl of Lauderdale (1759-1839), *Inquiry into the Nature and Origin of Public Wealth* . . . (1804). This is the only publication of his that counts as an analytic performance.

of Wellington . . . 1829), which was based upon an argument against excess saving and for excess expenditure.[20] The topics of value, capital, and interest owe something to him, as we shall see, but more important than are these contributions in themselves is the invigorating impulse he gave: he was a man who thought for himself and was not prepared to accept fundamentals as handed to him by the Smithian tradition. Though a dilettante and, from the standpoint of the nascent profession, something of an outsider, he was a writer of force and, in most cases, of sense.[21]

The only author who ever did justice to Ramsay is Marx, who dealt fully with him in the *Theorien über den Mehrwert*.[22] Even Professor Seligman, who revived his memory (op. cit.) emphasized his dependence upon French writers more than I think justified. It is true that, especially in his theory of enterprise and profits, he had been anticipated by Say. It is also true that he was not the first to introduce those ideas to English economics, and that he might even have 'borrowed' at second hand. But he synthesized better than did others and, more important, many suggestive details were his own. It is easy enough to see that he made no mark. But it should be added that he came near to doing so and that his lack of success has perhaps more to do with his unpopular opposition to the repeal of protection to agriculture than with his most serious shortcomings. There is thus no reason to think little of him.[23]

Read [24] impaired his chances of success by certain oddities, especially by his doubtful speculations about the 'Right to Wealth.' His attacks upon the Ricardian socialists are of little interest to us. Nevertheless his work is of some importance for us, first, because it bears witness to the influence of Bailey, whom Read followed in his Ricardo criticism, and to the anti-Ricardian current that was running strong around 1830; second, it has some merit and in turn exerted some influence of its own, particularly in the analysis of profit and interest. Among the writers it influenced directly, the most eminent one is Scrope,[25] the monetary reformer of index-number fame, who was not only the author of numerous pamphlets on money and banking, poor laws, agricultural labor, and other topics but also an economic theorist of some importance. His *Principles of Political Economy* (1833) was, however, written for popular consumption and did not develop his analysis at all satisfactorily. It is easy to notice his original ideas on population and the 'tabular standard.' But these are not what I mean just now. Much more important for us is the insight into the nature of economic equilibrium: he saw how the mechanism of demand and supply, turning on everybody's tendency to maximize returns, solves both the problem of allocation of resources (production) and the problem of income formation (distribution), thus disposing, incidentally, of the whole West-Ricardian construction. In the analysis of interest and profits, too, he made headway: it is there that he seems to have owed something to Read.

---

[20] On this, see F. A. Fetter, 'Lauderdale's Oversaving Theory,' *American Economic Review*, June 1945.

[21] Of late, an attempt has been made to 'explain' both his analysis and his recommendations in terms of his interests as a landlord. We know what to think of the explanatory value of this.

[22] Marx's recognition of Ramsay must, of course, be appraised with reference to his habits of criticism. If these are taken into account, this recognition means a lot. Also it speaks highly of Marx's scholarship, for when he wrote Ramsay was practically forgotten. Sir George Ramsay's (1800-1871) only relevant work is his *Essay on the Distribution of Wealth* (1836).

[23] Ramsay's case is food for thought, particularly in one respect: when a writer has failed to make the right contact with his contemporaries—excepting those rare cases in which a valiant champion arises to laud him to the skies posthumously—historians assume a strange attitude of hostility toward him and set up standards that would dwarf A. Smith, whereas, in more fortunate cases, they quite commonly sponsor absurd claims to originality or other merits that are never revised.

[24] Samuel Read (no personal data that I know of); the only work that needs to be mentioned here is his *Political Economy. An Inquiry into the Natural Grounds of Right to Vendible Property or Wealth* (1829). E. R. A. Seligman (op. cit. sec. 4) has noticed all the points about it that matter to us.

All the performances so far mentioned in this section—and our list is very incomplete—were un-Ricardian or anti-Ricardian; and it would be quite impossible to draw up a parallel list of Ricardian writings. Moreover, the antagonism to the West-Ricardian schema that all of them display was primarily scientific and not political: Read's hostility to the Ricardian socialists may have set him against the Ricardian theory of value, but for the rest I cannot find *motivating* political antagonisms between these writers and the Ricardians.[26] The theory that resolves all differences between economists into differences of their politics and always looks to 'what a man stands for' fails in this case as it does in the case of the victory of the marginal utility theory in the next period. Finally, the writings of which we have noticed examples put later developments in a new light: a continuity of effort reveals itself to anyone who pays attention to these writings that is completely lost in the usual story of a prevalent Ricardianism—J. S. Mill figures as a Ricardian in this story—spectacularly shattered by 'revolution' around 1870.

The last author I am going to mention, Torrens,[27] cannot be described as anti-Ricardian. But neither can he be described as a Ricardian. Professor Seligman has argued the case for Torrens' independent discovery of the 'Ricardian' theory of rent, with priority over Malthus and West, and of the principle of comparative cost, with priority over Ricardo. On the one hand, this is enough to secure him a place in the history of analysis; on the other hand, this seems to include him in the Ricardian group. His exploits in general theory, however, are distinctly un-, if not anti-, Ricardian. But they are difficult to appraise because Torrens was careless in formulation and not a good technician and offers his wheat much mixed with chaff. He did not accept the central Ricardian doctrine that issues in the proposition that profits depend exclusively on wages. But his argument against it strongly suggests that he failed to grasp the sense in which Ricardo held it. What he put into its place may have been substantially valid as he meant it. But as it stands, it is not particularly enlightening. He needs an interpreter to do for him what the Ricardo admirers of around 1890 did for Ricardo. Until such an interpreter appears and succeeds it is premature, to say the least, to rank him, as has been done in one instance—presumably in reaction to the contemptuous treatment he received on other occasions—with Ricardo and Malthus as one of the 'founders of the classic school.'

---

[25] George Poulett Scrope (1797-1876) was one of those delightful Englishmen of laborious leisure to whom our science, like others, owes so much. Among other things, he was an authority on volcanoes and a M.P. His reputation as an economist rests mainly on his work on central-bank policy and on stabilization of the price level. But there is also *analytic* merit—and striking independence and originality—in some of his pamphlets on other practical questions. Though accepting the fundamental slogans or principles about the 'system of natural liberty' current in his time, he bravely swam against the stream in such matters as his unemployment-insurance scheme and his advocacy of public works. When dates are considered, the insight—I repeat: the *analytic* insight—implied in this places him high above the common run of the economists of his time.

[26] Ramsay's qualified support of the corn laws, e.g., can be defended also on a Ricardian basis. This is why I italicized the word *motivating*.

[27] Another strong, interesting, and sympathetic type! Colonel Robert Torrens (1780-1864), a professional soldier who had seen service, finding himself on half-pay after the Napoleonic Wars, proceeded forthwith to make for himself a fresh career in politics and finance and a name as an economist as well. He is chiefly known for his advocacy of Peel's Act: excepting Lord Overstone, he was the only economist of standing who

4. FRANCE

If French economics of that period is to be seen in its true proportions, two facts must be borne in mind. First, as we know, the Parisian scene was colored until 1848 by the activities, literary and other, of socialist groups to an extent for which there is no contemporaneous parallel anywhere else. Not so spectacular but equally important in the long run were the activities, also literary and other, of Catholic critics of economic and political liberalism ('the principle of 1789'), which went, however, beyond criticism toward the goals of Catholic social reform.[1] Laicist bourgeois of ultraliberal persuasion formed a third group. All this makes fascinating material for the sociology of political and social ideas. But it makes poor material for the history of scientific eco-

---

identified himself with it. Like Scrope, he wrote a great many pamphlets and 'letters' on topics of the day. The marvel is that he also ascended into the rarified air of pure theory. The writings that are important in this respect are: *An Essay on the External Corn Trade* (1815); *An Essay on the Production of Wealth* (1821); *On Wages and Combinations* (1834). See Seligman and Hollander, 'Ricardo and Torrens,' *Economic Journal*, September 1911.

[1] I am going to use this opportunity to mention Alban de Villeneuve-Bargemont (1784-1850; especially: *Économie politique chrétienne*, 1834), a central figure in a broad movement. It is extremely difficult to do justice to his work. Those—laicist liberals in particular—who look at his social philosophy and his politics, decide whether they like it or not, and appraise him accordingly have indeed an easy task. But ours is not so easy. We have to realize, first, the depth and social significance of his convictions; the wisdom of many of his practical recommendations; the scientific value of much of his sociology; and, at the same time, the defects of his technical economics, which was in fact rudimentary. These defects should not decrease in the least our respect for the man *or his thought;* only, they happen to be relevant from the standpoint of this book.

nomics. Second, excellent factual work was done during the period, the great performance of Le Play topping a highly creditable record. For the rest, however, there are only two first-rank men to mention (besides Cournot of course), namely, J. B. Say and Sismondi.

Jean-Baptiste Say (1767-1832) was one of those men who illustrate two important though slightly paradoxical truths: first, that, in order to appraise a man properly and to put him into the right place, it is sometimes necessary to defend him not only against his enemies but also against his friends and even against himself; second that there is a fundamental difference between superficiality of exposition and superficiality of thought.[2] Superficiality is in fact what strikes Say's reader first. His argument flows along with such easy limpidity that the reader hardly ever stops to think and hardly ever experiences a suspicion that there might be deeper things below this smooth surface. This brought him sweeping success with the many; it cost him the good will of the few. He sometimes did see important and deep-seated truths; but when he had seen them, he pointed them out in sentences that read like trivialities. He never bent—as even Ricardo did—to the task of hammering them out so that they might be recognized by everyone for what they were and stand criticism and wear and tear. Also he invariably mismanaged his case in controversy by replying to criticism in a desultory manner, without bestowing the requisite amount of work on it. Hence, the historian must restate his argument for him and, in doing so, must often neglect infelicitous wording or even discard downright silly bits of reasoning that only carelessness will account for. Everyone realizes that this must also be done for Ricardo and Marx because, in their cases, the roughness of the surface invites digging. But the economists were few indeed who were able and willing to render this service to Say.

Thus he never got his due. The huge textbook success of his *Traité*—nowhere greater than in the United States—only confirmed contemporaneous and later critics in their diagnosis that he was just a popularizer of A. Smith. In fact, the book got so popular precisely because it seemed to save hasty or ill-prepared readers the trouble of wading through the *Wealth of Nations*. This was substantially the opinion of the Ricardians, who treated him with some respect because of the Law of Markets, which they accepted from him,[3] but for the rest put him down as a writer—see McCulloch's comments upon him in the *Literature of Political Economy*—who had been just able to rise to Smithian, but had failed to rise to Ricardian, wisdom. For Marx he is simply the 'insipid' Say (*der fade Say*). For later critics he was merely one of the exponents of economic liberalism to be disregarded on this count alone. Where he did live on, in the theory of cycles, his law was voted either wrong or else a valueless tautology. In our own time he experienced a curious kind of renaissance. His Law of Markets was declared—mistakenly as we shall see—to be the basis of the whole structure of classic economics in the Keynesian sense of this term (see above, ch. 1, sec. 1). This gave him sinister importance—but at least it gave him importance.

---

[2] Let me illustrate this: nobody will call Hegel's exposition superficial, but some (misguided) individuals may think that his elaborate show of profundity covers many shallows. J. B. Say, as will be argued in the text, presents an instance of the opposite kind.

[3] Even as regards this law, they displayed some inclination to assert claims of their own (on behalf of James Mill), although Say's priority is beyond the possibility of doubt.

But even his friends were taken in by that deceptive semblance of superficiality. Even for those French historians who were ready enough to protect his memory, he was primarily the exponent—one of them said 'vulgarizer'—of A. Smith's teaching. To this merit, it is true, they added various others, of which we may take notice by anticipation: Say cast the subject matter of economics into the schema—production, distribution, and consumption; its methodology owes something to him; he pointed toward a utility theory of value; he helped to establish the triad of factors—land, labor, and capital; he emphasized the figure of the entrepreneur, using the term (which occurs in Cantillon); and, of course, he was Say of Say's Law of Markets. All of this, as usually put, makes only a modest case since some of these merits are per se of minor importance or even of doubtful value. We shall comment on all of them in due course. At present, we are concerned with the fundamental error that vitiates appraisal of Say's position in the history of economics, namely, with the usual interpretation of his relation to A. Smith.

Say's work grew from purely French sources, if we consider Cantillon a French economist. It is the Cantillon-Turgot tradition, which he carried on and from which he *could* have developed—whatever it was he actually did—all the main features of his analysis including, by the way, his systematic schema and his entrepreneur.[4] The most important of these features, and his really great contribution to analytic economics, is his conception of economic equilibrium, hazy and imperfectly formulated though it was:[5] Say's work is the most important of the links in the chain that leads from Cantillon and Turgot to Walras.

Only two facts about his life are relevant to our purpose. Barring some unimportant cases during the French Revolution, he was the first French academic teacher of economics, first at the Conservatoire National des Arts et Métiers (1819), later at the Collège de France (1830). And, for a considerable part of his life, he was a practical businessman and thus enjoyed the advantage of having first-hand knowledge of what he was writing about. Intellectuals who know business only from newspapers are in the habit of congratulating themselves on their detachment. But obviously there is also another side to the matter. The principal items in his list of publications for us are his *Traité d'économie politique* (1803; Prinsep's trans., 1821, is from the 4th edition which, however, it is dangerous to use without also referring to the 1st, for Say had a way of forgetting what he really meant) and his letters. The *Cours complet d'économie politique pratique* (1828-9) does not add a great deal. His works (*Oeuvres*) form vols. IX-XII of the Guillaumin *Collection des principaux économistes* (1840-48). The *Traité* needs no reader's guide. But I wish to reiterate the warning that profitable perusal is much more of a job than it looks.

---

[4] Although I am pleading for justice to him, I must emphasize that, to some extent, this reduces his claims to originality. The Cantillon tradition had never died out in France.

[5] In part, the imperfections alluded to are due to the fact that the task is an essentially mathematical one, which he was not equipped to handle. This adds to the difficulties of doing justice to him also in other respects: his Law of Markets is expressed in loose words that may be made to carry different exact meanings.

J. C. L. Simonde, who called himself 'de Sismondi' (1773-1842), was something of a practical farmer and an amateur politician—excellent exercises in realism—but primarily a laicist intellectual, who enjoyed living on the fringe end of *le monde*, and a historian. His main achievement is, I think, his *Histoire des républiques italiennes du moyen âge* (1807-18). Of these 16 volumes, I have a skipping knowledge, which is, however, more than I can say with reference to the 31 volumes of his *Histoire des Français* (1821-44). Of the rest of his historical work, which also covers literary history, I know only his *Histoire de la chute de l'empire romain* . . . (1835), the scholarly shortcomings of which are partly compensated for, to an economist, by interesting sociological vistas and analyses. His economics are much more English than French. His *Richesse commerciale* (1803), is indeed not quite the Smithian brew it has been made out to be, even if we disregard the un-Smithian recommendations in the second volume. The real Sismondi, the Sismondi of later years, shows occasionally. On the whole, however, the traditional opinion is sufficiently near the truth. Sismondi's reputation as an economist rests on his *Nouveaux Principes d'économie politique* . . . which appeared in 1819.[6] But we know that the essentials of this work had actually been written by 1815 for an article that Sismondi contributed to Brewster's *Edinburgh Encyclopaedia*, though this article was not published until after the *Nouveaux Principes*. By then—at the latest—he was in possession of all the elements of doctrine that are associated with his name. His later works, such as his *Études sur l'économie politique* (1837-8), emphasized and developed the main points—and his claims—but do not add anything essentially new.[7]

Sismondi's work received critical notice immediately, especially from the Ricardians. As the tide went against the latter, Sismondi's fame increased steadily until, with social reformers and opponents of laissez-faire in general, he was eventually raised to one of those positions to which it becomes etiquette to pay respect. In part, this was owing to attitudes that have little to do with analytic achievement; he preached the gospel that the true object of economics is man and not wealth. He attacked Ricardianism as mere 'chrematistics' and as unrealistic chrematistics to boot.[8] He advocated once more the intervention of the state in economic affairs. And he was thoroughly pro-labor. Whoever did any or all of these things was as sure of applause from some quarters as he was of adverse criticism from others. But it must be added that he was in fact one of the most important forerunners of later *Sozialpolitik* and that some of his recommendations—for example, the recommendation that employers should be made to guarantee their workmen security against unemployment, sickness, and destitution in old age—are among his most genuinely original contributions.[9] As regards analytic economics, his reputation rests primarily upon his argument against Say's law and his underconsumption theory of crises (if indeed his theory should be thus labeled; see below, ch. 7, sec. 6). But even if the uncritical recognition that was extended to him on this score—mainly by economists whose strength was not in economic theory—were more justified than it is, these points would not express his true importance in the history of analysis.

---

[6] The 2nd edition of the *Nouveaux Principes* came out in 1827 with not insignificant changes.

[7] Selections of Sismondi's works have been published in German with an introduction and comments by Professor Amonn (1945-9). See also A. Aftalion, *L'Oeuvre économique de Simonde de Sismondi* (1899); and H. Grossman, *Simonde de Sismondi et ses théories économiques* (1924).

[8] Sismondi never lost an opportunity to extol A. Smith at the expense of the 'new school' (the Ricardians). In matters of method, he diagnosed A. Smith's as truly scientific and 'experimental' (meaning empirical), whereas he condemned Ricardo's as abstract

The distinctive feature of Sismondi's analysis is that it is geared to an *explicit dynamic model in the modern sense of this phrase*. The terms, Static and Dynamic, we have met already. We shall use this opportunity to take a first step toward a closer acquaintance with their meaning. For this purpose, let us start with a famous statement of Ricardo's, made in a letter to Malthus: [10] 'You always have in mind the immediate and temporary effects . . . [I] fix my whole attention on the permanent state of things which will result from them.' This is not quite true, but if it were, it would mean this: suppose we have before us an economic process that is perfectly balanced and ideally adapted to its data; then let us impose arbitrarily some change in some element or elements of it, say, in some prices or quantities; this disturbance will produce immediate adaptations, some of which will in turn produce further disturbances; but in the end, when everything has had time to straighten itself out, a new perfectly balanced state of the economic organism will result that is again ideally adapted to its data.[11] Ricardo was evidently of the opinion that the important thing is to investigate the properties of this new 'normal' state *in comparison with the properties* of that 'normal' state from which we started: the new 'permanent' incomes, prices, and quantities are compared with the old incomes, prices, and quantities. For this procedure, the term Comparative Statics came into use later on (see below, Part

---

speculation that had lost contact with reality. It should be observed, however, that his arguments, so far as they are valid against Ricardo, are just as valid against Smith.

[9] The more limited modern idea of the 'guaranteed wage' may with justice be said to have been visualized by him. The originality of his suggestions stands out in one point especially: his idea was to turn the social costs of labor-saving improvements into business costs of employers.

[10] Professor Hollander quoted this letter in his Introduction to Ricardo's *Notes on Malthus' Principles* (ed. 1928, p. lxxxviii).

[11] This is by no means always so and, even if it is, requires proof that raises a number of delicate questions. Just now we neglect this, just as Ricardo himself neglected it.

IV, ch. 7, sec. 3). It implies, of course, both that the sequence of intermediate or 'transitional' states through which the system has to pass on its way to the new 'normal' state does not affect the latter—that is to say, that the new 'normal' state depends only on the old 'normal' state and on the nature of the disturbance but *not* on that sequence of transitional states—and also that the transitional states are relatively unimportant, at least in the sense that they do not present any very interesting problems to the analyst.

Sismondi admitted, just as uncritically as had A. Smith and Ricardo, that such a new equilibrium state—he used the term equilibrium—will eventually emerge. But he urged that the road toward it may be so long and lead through such severe upheavals—he said: 'terrible sufferings'—as to make it practically impossible for the analyst to deal cavalierly with the incidental phenomena. So far, so good. Malthus did (independently) the same thing. But Sismondi took a further step, credit for which he does not have to share with Malthus or anyone else except, possibly, with Quesnay. He realized that the most important of the reasons why transitional phenomena are of the essence of the economic process—and hence not only relevant to its practical problems but also to its fundamental theory—is that the economic process is chained to certain sequences that will exclude certain forms of adaptation and enforce others. An example will help. If the money income generated by a given process of production were always to be spent on the output of this same process of production, we should have a reason to believe[12] that the public's 'purchasing power' and the output of goods and services would, barring individual errors, always correspond to one another so that, *at least as a possibility*, the latter could always be sold at cost-covering prices. But suppose that the economic process is chopped up into periods in the following way: the money income of any period t is generated by processes of production, the output of which becomes available in period $t + 1$; and this same income is spent in period t on the output of the period $t - 1$. In this case, we lose one of the reasons we have for believing that income and output will correspond to each other in the sense mentioned above: the money income of period t is the result of decisions taken in period t, whereas the output offered in period t is the result of decisions taken in period $t - 1$, hence taken in possibly different circumstances—a fact that evidently may be a source of difficulties in adaptation and of new phenomena incident thereto. The example is oversimplified and otherwise unrealistic. But it suffices to show that the economic process is a system of periodicities and lags and, by virtue of this alone, harbors a world of problems that simply do not exist for Ricardian economics or any other economics of the same type. Analysis that takes account of this fact and attempts to deal with these problems is called dynamic analysis. We shall have to attend to it later on (Part IV, ch. 7 and Part V). Now we shall break off an argument that has, for the moment, no other purpose but to define the distinctive feature of Sismondi's analysis.

---

[12] This condition would not be sufficient. However, in order to make my point as simple as possible, I neglect this fact here.

Nobody can ever have been unaware of the facts at which we have just glanced. A long list of pieces of analysis could be compiled, from mercantilist times on, that contain, unsystematically and rudimentarily, some dynamic elements. Even Ricardo would be represented in this list. But Sismondi's great merit is that he used, systematically and explicitly, a schema of periods, that is, that he was the first to practice the particular method of dynamics that is called period analysis. Moreover, he saw clearly the difference this makes and in particular the disturbances, discrepancies, and hitches that result from the fact that economic life is bound to sequences of which every unit is determined by the past and in turn determines the future. At the same time, this great analytic merit is his only one. He handled his own tool—like other ideas of his—so clumsily as seriously to impair its usefulness. And all the other arguments he adduced against the Ricardian system, and for the propositions that he tried to put in place of it, were technically so faulty as to make it easy for the Ricardians to dispose of them and even to take him not quite seriously. Thus, we have before us, once more, one of those situations where a man was *rightly* defeated and, on another level of discourse, was nevertheless right. The Ricardian judgment about him prevailed also with the non-Ricardians of the second half of the nineteenth century. And the applause of those who appreciated his fervent social sympathies or the mere fact that he found hitches in the capitalist process was, so far as scientific economics is concerned, no compensation for this—for the competent theorist this applause was rather in the nature of a verification of his own adverse opinion.[13]

In the chair at the Collège de France,[14] Say was succeeded by the Italian Rossi, Rossi by Chevalier,[15] whose tenure extended to 1879, and Chevalier, in turn, by his son-in-law, Paul Leroy-Beaulieu, whose career covers practically the whole of the next period. This academic succession should be noticed because it was also a succession in spirit and doctrine. In the high heavens, Say's true successor was indeed the great Walras. But on a less exalted level and as to 'applied' economics, attitudes in economic policy, systematic arrangement, and also as to the lower ranges of economic theory, these men (Rossi less than the other two) may be considered as followers of Say and as the core of a school which, if we date it from 1803, the year of the publication of Say's *Traité*, boasts of a history of about a century. We shall consider it in the next Part. For the present, besides noting that interesting fact itself, we confine ourselves to the following comments. First, so far as nonsocialist economics is concerned, this group was not to meet significant opposition until the next period. During the period under discussion and a little beyond, it ruled supreme, controlling in particular the professional journals and institutions, and also the Société d'Économie Politique which was founded, like the *Journal des économistes*, in 1842. Second, the school and all its members were —partly, as has been mentioned before, owing to the presence until 1848 of a strong socialist menace to bourgeois society—strongly liberal in the laissez-faire sense and anti-*étatistes*.[16] This naturally accounts for the hostility of modern critics that also reflects upon Say himself, but it should be unnecessary to point out that their derogatory judgments are unhistorical. Third, the school had many members of admirable character, strong intelligence, and great experience in practical affairs. But, fourth, owing partly to the practical turn of their minds and their too exclusive concentration upon economic policy, they lacked interest in purely scientific questions and were in consequence almost wholly sterile as regards analytic achievement. Their very existence as a

---

[13] As an illustration of Sismondi's technical incompetence, I refer the reader to his numerical argument on pp. 374-84 of the first volume of the *Nouveaux Principes*. Sismondi correctly perceived that his period analysis greatly weakened the 'classic' argument about free competition. But then he tried to show by a numerical example how the competitive struggle leads to deadlock; and what his figures actually show is exactly the contrary—they display the mechanism by which the hitch will in general be avoided.

[14] The Collège de France is neither a college nor a graduate school in the American sense, though somewhat more like the latter than like the former. Appointment to a chair is an honor that spells recognition of the appointee's leading position rather than an opportunity for inspiring and directing research. Lectures are addressed to a wide public and sometimes are (or were) frequented by *le monde*.

[15] Michel Chevalier (1806-79) was undoubtedly one of the most eminent economists of that period—known to fame as the Chevalier of the Cobden-Chevalier commercial treaty between England and France (1860), which was followed by quasi-free-trade treaties between France and a number of other countries. His various activities, often

---

in the service of, but never in subservience to, the French government produced a respectable quantity of valuable work of a factual nature and, occasionally, singularly infelicitous predictions such as that gold would fall in value (in 1859!) and that universal free trade would be realized before the century was out. That factual work may be illustrated by his *Lettres sur l'Amérique du Nord* (1836) and his *Intérêts matériels en France* (1836), models of their type. It is, however, to be expected that, for sheer lack of time, such a man cannot have contributed to the efficiency of the apparatus of analytic economics, and that a history of analytic economics has to mention him mainly for the purpose of explaining why that apparatus showed so little improvement for decades together. It was not that economists were incapable. Chevalier, e.g., was beyond doubt a very intelligent man whose work of factual analysis, were comparison admissible, many of us would place above that of the mere analyst. But all the energies of many of the able men who took to economics were absorbed by the immediately practical—invested in a process of production that may be likened to primitive hunting. Chevalier's systematic work (*Cours d'économie politique*, 1st ed., 1842-4; a volume *La Monnaie* was added in 1850), the harvest of his lectures at the Collège de France that kept strictly on the surface of things, bears saddening witness to this—though, for the kind of performance it was, it merits admiration rather than contempt.

[16] Some of its members, Chevalier included, experienced however a Saint-Simonist spell in their youth.

group will appear to the modern radical as a bar to 'progress.' From a quite different standpoint and in a different sense, it likewise appears so to us.

But a few more names must be mentioned in further illustration. First, I shall mention two who stand out from the rest and illustrate the virtues of the school at its best, though they also illustrate its weaknesses, Dunoyer (1786-1863) and Courcelle-Seneuil.[17] Next we notice J. A. Blanqui and Joseph Garnier, meritorious workers[18] who met with success in their own day as well as later: both, but especially Garnier, kept on being quoted. Third, Destutt de Tracy, also, has been too often quoted, though mainly in the literature of his own time, to be passed by completely.[19] A few others will be mentioned as occasions arise. But no occasion will arise to mention Canard and Bastiat. So their names may as well stand here.

---

[17] Admirable men both of them, who always stood uncompromisingly for what they considered the right course for their nation to take! But in spite of all the genuine brilliance—coupled with strong sense—that we find in Charles Dunoyer's *De la Liberté du travail* (1845), we cannot rank it as a scientific performance. Socialists will agree with us on the ground that his every sentence was ideologically conditioned and served some 'apologetic' purpose. But it is not this which motivates our own judgment. If it were, we should have to exclude practically all socialist writings that are not less ideologically conditioned. The book adds nothing either to our knowedge or to our control over facts. The case of J. G. Courcelle-Seneuil (1813-92) is different. His *Traité théorique et pratique d'économie politique* (1858); *Traité . . . des entreprises industrielles, commerciales, et agricoles* (1855); *Traité . . . des opérations de banque* (1853), to mention only a few of the literary fruits of a busy life, were models of their kind and have served as such. Even if one does not attach much importance either to his rudimentary graphs or to certain unsuccessful terminological innovations of his (theory—plutology; applied economics—ergonomy), there is in his works that clear grasp of economic affairs that comes from firsthand experience and that one misses so much in the modern literature. At the same time, I do not think that it is possible to say more for him than this. His work illustrates our old truth that it is one thing to be a good economist and quite another to be a theorist.

[18] J. A. Blanqui (1798-1854), the brother of the revolutionist of the 'putschist' type, L. A. Blanqui, was also an academic successor of Say, viz. at the Conservatoire National des Arts et Métiers. He is chiefly known for his *Histoire de l'économie politique en Europe* (1837), an interesting compilation that enjoyed international success because of its indubitable usefulness. Much more important was his *Résumé de l'histoire du commerce et de l'industrie* (1826), a judicious abstract that seems to me to be very well done (considering its date and the resources on which such an undertaking could then draw) and his researches into labor economics. Joseph Garnier, 1813-81 (not the Comte Germain Garnier, who is chiefly known as the translator of the *Wealth of Nations*, 1802, and as a late physiocrat and need not detain us further), was a pupil and close associate of Blanqui and an indefatigable teacher, scholastic administrator, and writer. His highly successful *Éléments de l'économie politique* (1845; entitled *Traité* from 1860 on; we may add his *Éléments des finances*, 1858, which also grew into a *Traité*) is chiefly interesting as a sample of French pre-Millian economics. His *Éléments de statistique* commands the same kind of interest. His annotated French edition of Malthus' *Essay on Population* (1845) is more significant. He had to be mentioned because it has been said—and, to judge by quotations, not without reason—that he enjoyed international reputation. It may be proper to add here the name of Charles Ganilh (1758-1836), who also continued to be quoted in that type of theoretical literature whose authors thought it necessary to preface whatever it was they had to say by a complete survey of the older writers who had pronounced upon their subject. His *Systèmes d'économie politique* (1809), an early history of economic thought, deserves to be noticed on account of its date as well as because it did not fall in, uncritically,

Canard's performance (N. F. Canard, *Principes d'économie politique*, 1801, a curious revival of Cantillon's *Trois rentes*) is sometimes listed among early contributions to mathematical economics (on the strength of a few algebraic formulae that mean nothing) but would otherwise partake of the blessings of deserved oblivion, had not a misfortune befallen it. This misfortune consisted in its being 'crowned' by the same French Academy that later on failed to extend any recognition to Cournot and Walras. And those Olympians who felt their neglect the more bitterly on account of the honor done to Canard visited him with a scathing contempt that bestowed upon him an unenviable immortality: in the history of scientific bodies, Canard is forever sure of a place. The book is, however, far from being the worst that was ever written. It had some influence on Sismondi.

---

with the prevailing current of Smith-Say free trade. His *Théorie de l'économie politique* . . . (1815) is redeemed from complete insignificance by its 'realistic' or 'factual' quality.

[19] A. L. C. Destutt, Comte de Tracy (1754-1836) was a figure of some importance in the intellectual scenery of the Napoleonic Empire (and a little before and a little after)—a thinker by the grace of nature, though the latter had failed to add the gift of originality. He had, moreover, been formed in the eighteenth century world: and while such attention as his thought received is an interesting symptom of the survival of eighteenth-century attitudes, his thought itself is a not less interesting example of partially successful adaptation. Philosophically, he belongs in the Condillac tradition, politically—in spite of a number of critical reservations—among the many heirs to Montesquieu. His broadly conceived *Élémens d'idéologie* (the best translation I can think of is one into Scottish: *System of Moral Philosophy*) began to appear in 1801, a *Traité de la volonté* being one of the installments. Another installment of what was to remain a torso, was a treatise on economics, republished under this title (*Traité d'économie politique*) in 1823. With due respect for the spacious whole of which this treatise—which belongs to the Say group—was a component part, I have to confess that I cannot find in it anything to distinguish it except one feature: Destutt de Tracy was not a philosopher for nothing. He had an eye for logical rigor. Hence he insisted on neat conceptualization. One of his definitions—that production means change of form or place; Ramsay added time—was taken up by some English economists. But, by stressing what may be termed the physical aspect of production, it obscures the economic one. He also insisted that value must be measured in a value unit, it being the essence of measurement to compare the thing to be measured with a given quantity of the same thing chosen as a unit (as, e.g., length is measured in meters). Ricardo quoted this statement approvingly, but it is misleading. Other examples could be quoted in order to show that his preoccupation with logical foundations, which might have produced useful results, remained sterile.

Frédéric Bastiat's (1801-50) case has been given undue prominence by remorseless critics. But it is simply the case of the bather who enjoys himself in the shallows and then goes beyond his depth and drowns. A strong free trader and laissez-faire enthusiast, he rose into prominence by a brilliantly written article, 'De l'influence des tarifs français et anglais sur l'avenir des deux peuples' (*Journal des économistes*, 1844), which was grist to the mill of the small group of Paris free traders who then tried to parallel Cobden's agitation in England. A series of *Sophismes économiques* followed, whose pleasant wit—petition of candlemakers and associated industries for protection against the unfair competition of the sun and that sort of thing—that played merrily on the surface of the free-trade argument has ever since been the delight of many. Bastiat ran the French free-trade association, displaying a prodigious activity, and presently turned his light artillery against his socialist compatriots. So far, so good—or at any rate, no concern of ours. Admired by sympathizers, reviled by opponents, his name might have gone down to posterity as the most brilliant economic journalist who ever lived. But in the last two years of his life (his hectic career only covers the years 1844-50) he embarked upon work of a different kind, a first volume of which, the *Harmonies économiques*, was published in 1850. The reader will please understand that Bastiat's confidence in unconditional laissez faire (his famous 'optimism')—or any other aspect of his social philosophy—has nothing whatever to do with the adverse appraisal that seems to me to impose itself, although it motivated most of the criticism he got. Personally, I even think that Bastiat's exclusive emphasis on the harmony of class interests is, if anything, rather less silly than is exclusive emphasis on the antagonism of class interests. Nor should it be averred that there are no good ideas at all in the book. Nevertheless, its deficiency in reasoning power or, at all events, in power to handle the analytic apparatus of economics, puts it out of court here. I do not hold that Bastiat was a bad theorist. I hold that he was no theorist. This fact was bound to tell in what was essentially a venture in theory, but does not affect any other merits of his. I have said nothing of the charge that he plagiarized Carey that was urged by Carey himself, and then by Ferrara and Dühring. Since I cannot see scientific merit in the *Harmonies* in any case, this question is of no importance for this book. But readers who do take interest in it are referred to Professor E. Teilhac's balanced and scholarly treatment of it in *Pioneers of American Economic Thought* (English trans. by Professor E. A. J. Johnson, 1936). His argument establishes, with considerable success, that much that seems at first sight unrelieved plagiarism is accounted for by the French sources that Bastiat and Carey had in common. Bastiat's *Oeuvres complètes* with a biography were published in a second edition (1862-4).

For the rest, we must be content to notice what I believe to be one of the best textbooks of 'classic' economics, Cherbuliez' *Précis*.[20]

5. GERMANY

In the German section of our picture we see first of all the old 'cameralist' tradition—the tradition of the German Consultant Administrators—in a process of partial transformation under the influence of A. Smith. Though translated for the first time immediately after publication (1776-8), the *Wealth of Nations* took time to become effective. The profession of the *Staatswissenschaft* did not at first like it much, and, as has been mentioned before, some were inclined to put Steuart's *Principles* above it. But they experienced a very thorough change of heart around 1800, when first a few and before long a majority turned enthusiastically Smithian. This was in fact more natural for them than had been the initial resistance because, as has also been mentioned, their own ideas had been moving on similar lines for many years before that.

The works of Hufeland, von Jakob, Kraus, and von Soden suffice to exemplify this Smithian cameralism: Gottlieb Hufeland (1760-1817), *Neue Grundlegung der Staatswirthschaftskunst* . . . (1807-13; the second volume, on money, is rather interesting); L. H. von Jakob (1759-1827), *Grundsätze der National-ökonomie* (1805, enlarged and improved later on); C. J. Kraus (1753-1807), *Staatswirthschaft* (1808-11); Count F. J. H. von Soden (1754-1831), *Die Nationalökonomie* (1805-24). Jakob and Kraus were also philosophers (Kantians). All four were Smithians in the sense that almost all their thought and work in economics fed and turned upon the *Wealth of Nations*. Kraus, an influential teacher, who instilled his opinion into many future public servants,[1] embraced it with uncritical enthusiasm: he spoke of it as the only 'true, great, noble, and beneficent system' and was one of those who compared it to the *New Testament* in importance. Hufeland and Jakob, though Smithian enough, did not go quite so far as this; von Soden was still more independent. His criticisms of A. Smith were not well taken but he occasionally followed lines of his own. In particular, he adumbrated the idea, later on developed by List, that the true aim of foreign trade or any other policy was not so much immediate gain in welfare but rather the development of the nation's productive resources, a 'mercantilist' point of view, which is of importance not only for recommendation but also for analysis. All four were men of some eminence, and I am prepared to defend my choice. But the reader should understand that several other names might have served equally well.

---

[20] A. E. Cherbuliez (1797-1869), a Swiss lawyer by training and for part of his life by vocation, later a politician and professor of economics, was at first a political scientist rather than an economist. He was past forty when he seriously turned to economics, and he never produced anything original. But he excelled at exposition and his *Précis de la science économique* . . . (1862), deserves notice as one of the high points of the textbook literature of that period. Its success was considerable, but rather below its merit.

[1] Some of those public servants co-operated in the Stein-Hardenberg legislation. There is thus a not uninteresting relation between the *Wealth of Nations* and that Prussian reformer, von Jakob, who taught at the University of Kharkov as well as at the University of Halle, acted as a consultant to official commissions in St. Petersburg, and did much toward spreading Smithian doctrine in Russia.

Two men should be added who are not usually listed as German economists. The one, Count G. F. Buquoy Longueval (1781-1851) was a very interesting man: a great Austrian nobleman, very wealthy, very radical (as an old man he took part in the revolution of 1848), a gifted dilettante in many fields, more than a dilettante in at least two (theoretical mechanics and economics). He wrote, among older things, a *Theorie der Nationalwirthschaft* . . . (1815; supplements 1816-19) and a tract on money and monetary policy, . . . *Ein auf echten Nationalcredit fundiertes Geld* . . . (1819), both of which are Smithian in their bases but contain several interesting and original suggestions, that of a managed paper currency among others. Man and writings are forgotten unjustly, so I think.

The other man to be added fared better and, having been discussed in his day in England and France, has kept a place in the history of our subject: H. F. von Storch (1766-1835), who, though a German by race and training, is usually treated as Russian because of his career in the Russian service. His historical and statistical studies on Russia should be mentioned first (especially: *Historisch-statistisches Gemälde* [picture] *des Russischen Reiches am Ende des achtzehnten Jahrhunderts*, 1797-1803). I have 'skipped' through the 9 volumes but am not competent to judge how far Storch succeeded in exhausting the possibilities offered by his materials. As regards his systematic work (*Cours d'économie politique* . . . 1815) and his venture in income analysis (*Considérations sur la nature du revenu national*, 1824) it should be pointed out that the factual bent of the former and the ethical commonplaces contained in it do not justify the habit of historians of doctrine of placing him—as a member or as a forerunner—with the later historico-ethical school. He was not more 'factual' than A. Smith, and to separate him methodologically from his English contemporaries only serves to blur contour lines: Senior's factual work is in the reports of royal commissions instead of in his *Political Economy* but this is no reason for speaking of irreconcilable methodological differences between the two. If Storch doubted the possibility of formulating universal laws about economic phenomena, he did so in a sense that Senior and J. S. Mill would have heartily approved, that is, in the sense that the concrete economic phenomena, as historically given, do not obey simple and universally valid rules. For the rest, his analysis may be best described by the term 'critical Smithianism': his bases and conceptual apparatus are substantially Smithian but Storch disagreed with both Smith and Say on a number of important points. Particularly as regards income analysis. Storch has some claim to being listed, along with Lauderdale, Malthus, and Sismondi, as a forerunner of Keynesianism and of similar tendencies that asserted themselves, on and off, later on. However, if I understand his argument in the *Considérations*, there is not much in it: like all the authors in that line, he neglected, as much as other people overstress, the equilibrating mechanisms in the capitalist process. But we shall return to this. For the present, I want to make sure that the reader does not forget this man: though he does not rank high as a theorist, he is a significant figure.

Smithianism, increasingly leavened with a little (often misunderstood) Ricardo and relieved of some of the older stuff about eighteenth-century administrative policy—this is the formula that characterizes the common run of German economics until and even a little beyond the end of the period under survey. This material took the textbook shape that proved satisfactory for decades in the work of Rau.[2] But from this level and far above it rose the performances of two men of remarkable talent and force, Hermann and Mangoldt. In deference to a curious habit of the German historians of economics, I add Bernhardi.

Considering that Thünen and Marx followed paths of their own that were not within sight of that common run, we might feel inclined to discount the reputation of F. B. W. von Hermann (1795-1868) on the ground that he stands out for lack of competition. There is something in this. Nevertheless, his *Staatswirthschaftliche Untersuchungen* (1832; enlarged ed. 1870; reprint 1924), though it has not made scientific history, largely merits the many compliments that have been paid to it, even by A. Marshall. Hermann's good sense saved him all the energies that others spent on their doubts about 'abstract methods' and that sort of thing, and his acute and balanced mind played unimpeded about the fundamentals of economic theory. His method was as simple as it was meritorious, considering the date of his book: he started from 'supply and demand' and proceeded to investigate the factors behind it. His neat conceptualization did the rest and the success was considerable: it is not generally realized that his work spelled a long stride beyond Ricardo. This suffices to characterize his merits as a theorist in a general way. But it does not do justice to his factual work (statistical and other), and it does not do justice to the man, who as politician, civil servant, and teacher has left his mark upon the formative years of Germany.

Hans von Mangoldt (1824-68) is much less well known. Nevertheless, this civil servant and professor (at Göttingen and Freiburg) was among the century's most significant figures in our field. Apart from his historical work on the industry of Saxony, there are two important contributions which we have to notice: his *Die Lehre vom Unternehmergewinn* (1855: substantially a rent-of-ability theory of entrepreneurial gain) and his *Grundriss der Volkswirtschaftslehre* (1863: the 2nd ed., published posthumously in 1871, leaves out the most original element in it, namely, the geometrical apparatus that Mangoldt devised for the theory of international values: but Edgeworth brought it to light again).

---

[2] K. H. Rau (1792-1870), professor first in Erlangen and then in Heidelberg, certainly had sound common sense, learning, and mediocrity. But if any other qualities are needed for the production of a successful textbook, he must have had them also. The many editions of his *Lehrbuch der politischen Ökonomie* (1826-37: 1st vol., theory [the 'laws']; 2nd vol., applied economics or economic policy, or *Polizeiwissenschaft;* 3rd vol.—the best—public finance) are less indicative of its sweeping success than is the fact that Adolf Wagner thought it worthy of being remodeled instead of being replaced by an entirely new one. As a teacher, Rau must stand high in the history of economics, although little can be said in favor of the book except that it marshalled a rich supply of facts very neatly—and that it was just what the future lawyer or civil servant was able and willing to absorb.

Theodor von Bernhardi (1802-87) owes his reputation to Roscher's history of German economics. I have called the habit of listing his name indefinitely a curious one because there is really no reason for it that will stand examination. The title of the work in question I had better give in translation: *Critical Essay on the Arguments that are being adduced for Large and Small Properties in Land* (1849). Bernhardi, an extremely intelligent layman of wide culture and experience, discussed those arguments no doubt very sensibly. But it was not this which aroused Roscher's enthusiasm. Bernhardi put his topic into a spacious—and specious—framework of general considerations about the social and economic backgrounds from which English 'classic' doctrines arose, showing their historical and sociological relativity and their limited validity—quite successfully of course—but also showing inability to realize the difference between views or recommendations on practical questions and theorems.

Since Thünen and Marx (if the latter should indeed be called a German economist at all) are noticed elsewhere, we are, for the rest, left with List and Rodbertus, on the one hand—it is slightly disconcerting to observe that Thünen, Marx, List, and Rodbertus were all of them nonprofessorial economists—and with Roscher, Hildebrand, and Knies, the members of what has been termed the Older Historical School, on the other.

Friedrich List (1789-1846) holds a great place both in the opinion and in the affections of his countrymen. This is owing to his successful championship of the customs union of the German States (*Zollverein*), the embryo of German national unity. What this association means to Germans cannot be understood by members of those fortunate nations for which the right to national existence and national ambitions is a matter of course. It means that List, like all those whose names are associated with that long and painful struggle, is a national hero. Far be it for me to criticize this attitude or to withhold admiration from List in any other respect except the one that unfortunately happens to be the only one that counts in this book. Even as a scientific economist, however, List had one of the elements of greatness, namely, the grand vision of a national situation, which, though not in itself a scientific achievement, is a prerequisite for a certain type of scientific achievement—that type of which, in our own day, Keynes is an outstanding example. Nor was List deficient in the specifically scientific requisites that must come in to implement vision if it is to bear scientific fruits: his analytic apparatus was in fact ideally adequate for his practical purpose. But the individual pieces of this analytic apparatus were not particularly novel.

List saw a nation that struggled in the fetters imposed by a miserable immediate past, but he also saw all its economic potentialities. The national future, therefore, was the real object of his thought, the present was nothing but a state of transition. He realized that, in an essentially transitional state of this kind, policies lose their meaning when they are geared to the task of administering an existing set of conditions that is visualized as substantially permanent. This he expressed by his doctrine of 'stages'—a felicitous device, so far as his educational purpose was concerned, but in itself not more than an old eighteenth-century idea. Furthermore, he realized (like Soden) that emphasis upon the national future modifies welfare considerations *ex visu* of the present. This he expressed by his doctrine of 'productive forces' (*Produktionskräfte*) that in his system hold place of honor as compared with the consumers' goods that can be made available at a given level of the productive forces—not unfelicitous, this, as an educational device but not much more than a label for an unsolved problem. Finally, as regards his best-known contribution to the education of German public opinion on economic policy, the infant-industry argument, this is clearly Hamiltonian and part of the economic wisdom that List imbibed during his stay in the United States. So fully Americanized had List become then that he actually advocated financing railroad construction by the issue of banknotes, for which practice there were only—and hardly wholly creditable—American precedents. It should be remarked, in passing, that List's argument about protection issues into the free-trade argument: if this is not obvious, we can convince ourselves of it by noticing the fact that J. S. Mill accepted the infant-industry theory, evidently realizing that it ran within the free-trade logic.[3]

This, I think, does justice to, and at the same time reduces to its proper proportions, List's analytic gifts and performance. Those who insist on making their hero the possessor of merits of all conceivable types have put his thought into spurious relations of the kind that create spurious history. He was an heir to eighteenth-century thought. He was an offshoot of romanticism. He was a forerunner of the historical school of economics. There is not more in all this than that everyone is heir to everything that went before him and a forerunner of everything that comes after him. He was a great patriot, a brilliant journalist with definite purpose, and an able economist who co-ordinated well whatever seemed useful for implementing his vision. Is this not enough? Of all his writings the *Outlines of American Political Economy* (1827) is the most interesting for us because it displays his system in its earliest stage of development. His mature work that grew out of this, *Das nationale System der politischen Ökonomie* (1841; English trans. 1885), remains a classic in the eulogistic sense of the word, all the comments above notwithstanding. A new and comprehensive edition of his works (*Schrif-*

---

[3] Incidentally, it may be remarked that to call List's plans 'nationalist' or 'imperialist' is to play upon double meanings in both cases.

ten, Reden, Briefe) has been published (1927-32) by the German List Society (List-Gesellschaft), which also publishes *List-Studien*.

Johann Karl Rodbertus' (1805-75) name also owes something to circumstances: on the one hand, he did not meet either the competition or the criticism he would have met in England; on the other hand, though he spurned class struggle and revolution and was fundamentally a conservative monarchist, he was also a votary of a certain type of state socialism that was acceptable to a large sector of the public. For the rest, his social and political philosophies, including the manual workers' natural right to the whole product of industry (on the time-honored ground that all commodities are products of, or cost, manual labor only), are no concern of ours. But certain recommendations must be mentioned because they shed light on the analysis from which they proceed. The proposition that it is the institutional pattern alone that deprives labor of part of 'its' product was reflected in his recommendation to change this institutional pattern by state action such as taxation (one of the first proposals, in the liberalist world of that age, to use taxation for purposes other than revenue) and to fix not only prices and wages but also property incomes. His theory of rent of land was reflected in, but is not essential to, an extremely sensible proposal that has had some practical effect in Germany, namely the proposal to substitute for the mortgage that embodies a capital claim a mortgage that embodies only the right to an annual payment. His theory of poverty and of cycles was reflected in the proposal, which sounds so modern, to eliminate both by a redistribution of incomes.

Rodbertus' analytic schema can be most briefly and at the same time most tellingly described in this way. Fundamentally, and in the same sense as Marx, he was a Ricardian. His analytic effort was an effort to develop Ricardian doctrine in a certain direction and was in essentials parallel to, though different from, Marx's effort. According to dates of publication, Marx could have derived inspiration from Rodbertus, particularly as regards the unitary conception of all non-wage incomes—Marx's surplus value and Rodbertus' 'rent'—which is a feature of both schemata. In the main, however, Rodbertus' example can at best have taught Marx how not to go about his task and how to avoid the grossest errors. Therefore, and also because Marx's theoretical developments seem to me to follow naturally from Ricardo's formulations—given the direction in which those developments were to aim—I do not think that there is any cogent reason for challenging Engels' repudiation of the idea that Marx had 'borrowed' from Rodbertus.

To call Rodbertus a Ricardian is, of course, to limit the range of his originality. In addition, there is W. Thompson's priority—such as it is—for any sort of exploitation theory, and Owen's for Rodbertus' labor notes (currency).[4] But neither amounts to much. For his own convenience, the reader should keep in mind the following three points that I mention here by anticipation as specifically characteristic of the caliber of Rodbertus' theorizing (all of which have found admirers, however): (I) his thoroughly untenable theory of rent;[5] (II) his factually and theoretically equally indefensible theory that the relative share of labor in the national dividend tends to fall in the course of capitalist development; and (III) his underconsumption theory of crises that is based upon the proposition that overproduction must periodically result from labor's inability to buy back a sufficient amount of its product owing to (II)—a type of underconsumption theory that should be, but unfortunately is not, beneath discussion. Sismondi, who has some passages that seem to point in the same direction, actually did much better than that. Rodbertus' most important works are: *Zur Erkenntniss unsrer staatswirthschaftlichen Zustände* (1842); *Sociale Briefe an von Kirchmann* (1850-51; English trans. as *Overproduction and Crises*, 1898; 2nd ed., 1908); *Zur Erklärung und Abhülfe der heutigen Creditnoth des Grundbesitzes* (1868-9). Other writings that are of interest to us, including letters that contain some important clarification, have been posthumously published from time to time. There is a considerable Rodbertus literature, mostly German. I mention only H. Dietzel's *Karl Rodbertus* (1886-8), which makes up by analytic competence what, owing to its date, it lacks in information. It was A. Wagner's championship that brought Rodbertus to the fore in the last two decades of the nineteenth century.

---

[4] With both Owen and Rodbertus, and in essentially the same manner, units of labor are not merely what units of gold are in a gold currency, but the mechanism of this labor money also serves to 'correct' values.

Reasons will be offered, as we go along, for believing that it is in the interest of a realistic picture of developments in our field to confine the concept, Historical School of Economics, to the age and to the group of Gustav von Schmoller (see below, Part IV, ch. 4). This implies that it is not good practice to speak of an Older Historical School, a term that has been introduced, chiefly for use in the polemic against Schmoller's 'historism,' to denote a group of writers who, while appreciating the importance of historical research, displayed no hostility toward 'theory.' I maintain that such a position does not constitute a distinctive characteristic and that the economists who are usually mentioned in this connection do not, in any useful sense, form a group, let alone a school. But we must notice these economists themselves: Hildebrand, Knies, and Roscher. The first,[6] a man of restless activity and considerable influence, comes nearest to having been a historical economist in the later and genuine acceptance of the term. Knies, one of the most significant figures of German economics, will be mentioned in our survey of the next period, to which his main work belongs. This work was in the field of economic theory, however, and his only title to a place in the older historical school rests upon a methodological *professio fidei*, which is very interesting as such but, considering his own practice, does not mean very much. It belongs in the period under discussion and will be noticed below (ch. 5, sec. 2b). Roscher,[7] who taught at the University of Leipzig for forty-six years, added to the influence which this implies the influence of many works that never fell below a highly respectable level: honest scholarship and sound common sense is written all over them, and the sympathetic understanding that his gentle and highly cultivated mind extended to all types of scientific effort helped to make them perhaps more useful to many generations of students than would have been more original productions. Marx poked insipid fun at him. There were those to whom he looked like an obstacle to advance. On the whole, however, there is hardly another economist of that period who enjoyed so nearly universal respect inside and outside of Germany. With complimentary intention, writers who found it difficult to credit him with original results have tried to find something original in his method or approach. This is how he got into the position of being considered either one of the 'founders' of a historical school in general or a leader of the so-called 'older' historical school. He invited this by speaking frequently of his historical method or standpoint. But we shall see later that there is not much in this and that he should be classified, so far as his analytic apparatus is concerned, as a very meritorious follower of the English 'classics,' though a follower who happened to have a particularly strong taste for historical illustration.

---

[5] Meaning now rent of land in the usual sense and not in Rodbertus' sense, in which rent means profits plus interest plus rent of land.

[6] Bruno Hildebrand's (1812-78) chief work, *Die Nationalökonomie der Gegenwart und Zukunft* (1848; new ed. by Gehrig, 1922), displays hostility to the concept of natural law (in the sense that makes economic laws epistemologically analogous to physical laws); it places emphasis upon the moral-science character of economics (his term was *Kulturwissenschaft* as opposed to physics, *Naturwissenschaft*) and on other features that recur in the programmatic pronouncements of the Schmoller school and also in Windelband's and Rickert's methodologies of the social sciences. In addition, he did historical research. But his own programmatic pronouncement at the head of the first number of the *Jahrbücher für Nationalökonomie und Statistik*, which he founded in 1862, was remarkable for catholicity and obviously not intended to start or to espouse a distinct methodological party. In any case, if we do wish to label him a historical economist, he should be called a forerunner of the Schmoller school rather than a member of that triumvirate that does not form any real unit at all.

I think the discussion above blocks out all the salient features of the scenery that it is necessary to keep in mind for our purpose. Incompleteness is essential in a venture of this kind and should need no excuse. But all the same it seems desirable to atone for the absence of three names that some readers may miss. I have already mentioned Lorenz von Stein, in connection with the economic interpretation of history, and should perhaps have included him in this sketch because his most important works were all first published within the period. I have transferred him to the next, however, since his influence was to increase considerably in the 1870's and 1880's. A similar reason motivated my transferring Albert Schäffle. But I am going to use this opportunity to comment briefly on Dühring who does not fit in anywhere else.

---

[7] W. G. F. Roscher's (1817-94) indefatigable industry turned out a large number of publications, of which we have already mentioned *Zur Geschichte der englischen Volkswirthschaftslehre im sechzehnten und siebzehnten Jahrhundert* (1851-2) and *Geschichte der Nationalökonomik in Deutschland* (1874), monuments of scholarship. Neglecting all other items of an impressive list, among them two additional contributions of his to the history of economics and several studies in economic history, I shall mention only his extremely successful *System der Volkswirthschaft* published in five volumes: *Grundlagen der Nationalökonomie* (1854; a 26th ed. appeared as late as 1922; English trans. 1878); *Nationalökonomik des Ackerbaues* . . . (1859; 14th ed., 1912); *Nationalökonomik des Handels und Gewerbfleisses* (1881; 8th ed., 1913-17); *System der Finanzwissenschaft* (1886; 5th ed., 1901); and *System der Armenpflege und Armenpolitik* (1894; 3rd ed., 1906).

Eugen K. Dühring (1833-1921) had to abandon a lawyer's career owing to failure of eyesight quickly followed by complete blindness, and thereupon embarked, on the one hand, upon an academic career and, on the other hand, upon an intellectual effort that resulted in the conquest of a vast domain extending from mathematics, mechanics, and theoretical physics in general, to ethnology, economics, and philosophy. The truly admirable—in fact almost unbelievable—feat was, however, that in several stretches of that vast domain he attained the mastery requisite for original achievement. In particular, he published a brilliant history of mechanics (*Kritische Geschichte der allgemeinen Principien der Mechanik*, 1873), which, when awarded an academic prize, drew from the judges the curious comment that the level of the work was far above what would have been necessary to win the prize; and, more important, it was appreciatively noticed by Ernst Mach (see preface to first edition of the latter's *Mechanics*). In the history of the anti-metaphysical and positivist currents of thought, moreover, he cannot fail to retain a prominent place. In another sphere of thought—that philosophy of life which corresponds to the earliest meaning of the term philosophy—he developed an attitude or system which we may like or not, but which is both interesting and original (he called it 'personalism'). And there is his social philosophy—or system of social reform—that is entitled to the same comment (he called it 'societary'; it has some affinity with that of Rodbertus). The reasons why this significant thinker should have met with little except rebuffs are to be found mainly in a temperament that was at the same time generous and aggressive and that, by ferocious attacks, made enemies of practically all the individuals and groups he noticed at all. He experienced a revival, however, in the 1920's. All this had to be said to make it quite clear that any disrespectful attitude toward him is entirely out of place, and also to protect what follows from misunderstanding.

In the field of economic sociology he has indeed a considerable performance to his credit, namely, the anti-Marxist theory—which is partly tenable—that many of the property relations of the capitalist era have resulted not from the economic logic of capitalism, but from an extra-economic sequence of political causation. But in no other respect, since we exclude political thought and policy recommendations, is there, for us, positive contribution to report. He was—strange to say, considering his achievement in mechanics—a bad technician. He had no awareness of the analytic weaknesses of such an argument as that capitalist property (for institutional reasons) keeps the working class at a level of minimum of existence and deprives it of the fruits of technological improvement (wherefore the state must step in to assure labor of its appropriate share—again an affinity with Rodbertus). He had an unbounded enthusiasm for Carey and went into paroxysms of rage about Bastiat's plagiarism: but he displayed no grasp of either the strong or the weak points in Carey's system. And since this is what matters to us, we shall have no occasion to mention him again. Of Dühring's works the following are in our field: *Carey's Umwälzung der Volkswirtschaftslehre und Socialwissenschaft* (1865); *Capital und Arbeit* . . . (1865); *Kritische Grundlegung der Volkswirtschaftslehre* (1866); *Kritische Geschichte der Nationalökonomie und des Socialismus* (1871); *Cursus* . . . (1873). See E. Laskine, 'Les Doctrines économiques et sociales d'Eugène Dühring,' *Revue d'histoire des doctrines économiques et sociales* (1912) and G. Albrecht, *Eugen Dühring* . . . (1927).

6. ITALY

The political and administrative structure of every nation reflects itself in the organization of its scientific work. Thus, like everything else, scientific work was highly centralized in France. In England, quite different conditions produced a similar result: we find in every field, including economics, a relatively small and closely knit group within which severe selection operated to reduce to a few the names of real significance. Such structures are easy to describe. German economics, being much more decentralized, presented greater difficulties. Italian economics was still more decentralized. And I confess my inability to draw, in the available space, any satisfactory picture at all. All that can be said in general about the economic research, which was done during this period in the various centers of national life, is that it was not on the same level with the achievements of either the earlier times of Beccaria and Verri or the later times of Pantaleoni and Pareto. This shows in many ways, particularly in the dominating strength of foreign influence. The leads given by A. Smith, Malthus, Ricardo, and Say, whether accepted or subject to adverse criticism, were the starting points and material for work that was often able but primarily derivative. Hence also the characteristic interest both in Italian works of the past (the fifty volumes of Custodi's collection of the *Scrittori classici italiani di economia politica* appeared 1803-16)[1] and in the translation of foreign works (the 1st and 2nd series of the *Biblioteca dell'Economista* appeared, 1850-68). This is all the more remarkable because examination of available facts reveals plenty of ability in the personnel of Italian economics. By way of illustration, I mention two men of conspicuous brilliance, Rossi and Scialoja, whose careers also point to the cause—we know it already and it is always the same story—of the relative weakness of the scientific performances of strong men.[2] Two examples of relative weakness of performance in economics that were simply due to width of range are Valeriani and Romagnosi.[3]

---

[1] In Spain we find the same phenomenon; Juan Sempere y Guarinos' *Biblioteca española economico-politica* was published 1801-21.

[2] I wish I could draw a picture of Pellegrino Rossi (1787-1848), whose failures in his many political activities reveal more ability than do the successes of other people. This Italian, who became a Swiss constitutional reformer and professor of Roman history, then a professor of economics and constitutional law in Paris and a Peer of France, then French ambassador to Rome, and then again Papal prime minister, produced among other things a *Cours d'économie politique* (1840-54; the 3rd and 4th vols.

More concentrated effort produced significant performance in the cases of Gioja and Fuoco in the earlier and of Messedaglia in the later part of the period. Gioja's[4] work may be described best as an attempt to rewrite the *Wealth of Nations* from the standpoint of the united Italy he visualized. Pearls are hidden in an unprofitable heap of rubbish—that is partly redeemed, however, by the statistical work it contains. It is easier to do justice to Fuoco.[5] He was a theorist of note who does not merit oblivion. In some pieces, for example the one on the use of the concept of limits in economics, he displayed considerable originality. His conception of economic equilibrium in some respects marked progress beyond Say's. He is regularly mentioned in Italian histories—mainly, however, in connection with his preoccupation with the theory of rent—but seems to have exerted no influence at all. This was different with Messedaglia.[6] I have chosen him for mention because of the

---

were published posthumously) that merited its success but does not merit any further mention in a history of analysis. All the vast cultural horizons, all the practical insights that show throughout, do not alter the fact that, analytically, it was diluted Ricardianism plus a little Say. Antonio Scialoja (1817-77) wrote a nondescript *I principii della economia sociale* (1840)—that was, however, very well written and correspondingly successful—and not much else. But he was 23 when this text came out! What could a man have done who was able to accomplish such a feat in the absence of politics, public service, and so on, all interspersed with imprisonment, exile, cabinet office.

[3] L. M. Valeriani (1758-1828) was something of a polyhistor and much admired in his time and country. The little steam he reserved for economics was put to good use, however, in his theory of prices (*Del prezzo delle cose tutte mercantili*, 1806), which could have taught Senior and Mill how to handle supply and demand functions. Italian historiography credits him (and Scialoja) with having used mathematics. But his (and Scialoja's) merit in this respect hardly goes much beyond the perception of a great possibility. Other Italians perceived this possibility, e.g. Fuoco. G. D. Romagnosi's (1761-1835) name survives in the history of law and criminology. He was also a philosopher and something of a mathematician and physicist. But his economic philosophies, which were of an anti-*étatiste* but equalitarian nature, are not worth our while—they may be described as the foothills of Italian utilitarianism.

[4] Melchiorre Gioja (1767-1829). *Opere principali* (all I know) were posthumously edited, 1838-40.

[5] Francesco Fuoco (1777-1841), *Saggi economici* (1825-7) and *Introduzione . . . dell'economia industriale* (1829). Another interesting piece of work that holds a position in the long controversy on the productivity of credit, *Magia del credito svelata*, was published in 1824, in pursuance of a curious business transaction by Welz, who posed as the author.

[6] Angelo Messedaglia (1820-1901) was professor of law and later on of economics and statistics in Padua and Rome. His quiet professorial life, which suffered interruption by political activity for a brief period only, had its share in his achievement as had his bent for patient research. But the divine spark was not lacking. He affords an excellent example for the study of the particular combination of gifts, tastes, and circumstances that make for solid scientific success and are adequate for reaching any ranks but the

strategic position he holds in the history of Italian economics and statistics. Maffeo Pantaleoni expressed, I believe, the opinion of a large majority of the Italian profession when he wrote that Messedaglia was one of the three men—the other two being Cossa and Ferrara—whose teaching formed 'all' (?) Italian economists of the subsequent period in which Italian economics was again to shine so brightly. This solid achievement rests on no one of his individual performances taken by itself, though most of them are of a high order of scholarship, for example, his monographs on public loans, population —only those two belong to the period—statistical theory, and money. More than by their individual contributions to their subjects, they influenced as messages of the spirit of scholarship and as examples of research that refuses to serve the day. We add Nazzani for the same reason that justifies inclusion of Cairnes with the English economists of the period—he was perhaps the most eminent Italian exponent of 'classic' theory and his chief contributions belong here in spite of their dates.[7]

Besides being woefully incomplete,[8] this sketch suffers also from the impossibility of giving due weight to the factual work done by Italian economists, particularly on agricultural problems including problems of ownership and tenancy, which would affect our impression considerably. But little can be done about this. Of texts, I shall mention, besides Scialoja's, also Boccardo's and the one I personally like best, de Cesare's.[9] The most conspicuous figure of Italian economics of that period and perhaps for twenty years beyond it, Ferrara, I left to the last. He was a great leader. He formed a school of his own. But affection and admiration for him has crystallized so as to lend to his figure enlarged dimensions.

> Francesco Ferrara (1810-1900) was primarily a scholar and teacher. But he was also a politician who played his role in the formation of a united Italy and in the task of organizing the new national state. I mention those activities and also his passionate interest in the issues of economic policy for two reasons. First, they explain why, like Ricardo, he speaks to us from a pedestal that did not consist of scientific achievement

---

highest. Any work of reference will supply the reader with a list of his publications, a few of which will be mentioned later on.

[7] Emilio Nazzani (1832-1904), *Sulla rendita fondiaria* (1872), republished with three other essays (wages, profit, English 'classics') in one volume, 1881.

[8] One of the many lacunae may be filled by mentioning the history of Italian economics, *Storia della economia pubblica in Italia* (1829), by Conte Pecchio, whom McCulloch—of all men—reproached for national bias!

[9] G. Boccardo (1829-1904), *Trattato teorico-pratico di economia politica* (1853), the answer to the student's prayer before exams. Another Millian treatise. Carlo de Cesare's (1824-82) *Manuale di economia pubblica* (1862), though also 'classic' fundamentally, was something more than that, much broader and deeper than Boccardo's. It was the work of an eminent man whose bibliography includes many an excellent report on many a thorny question—of one of those men who are invaluable servants to their nations, indeed so entirely given to this service that knowledge would never advance by a yard if there were not other mental types.

alone: Italians may well revere the great economist as one of the founding fathers of their state. Second, those activities and his attitudes in discussion of practical issues are very revelatory of his character: we behold a man of the most punctilious honor and conscience, impervious to any temptation—in environments that offered many—a single-minded lover of his nation, uncompromising to a fault; but we also behold a doctrinaire of almost unbelievable inflexibility. Economically and politically he was an ultra-liberal in the sense defined in the second chapter of this Part. And the slightest deviation from this ultra-liberalism was anathema to him. In this respect, like many liberals, he was tyrannically intolerant—a godsend for the opponent who knows how to make use of this trait. He never seems to have so much as tried to understand any standpoint but his own. *Sozialpolitik* simply roused his wrath. This is relevant for us because as he was in politics, so he was in science. He entertained an uncritical confidence in the powers of economic theory: hence the historical school, also, simply roused his wrath. Such leadership evidently has its dangers. But we must not forget its merits. Strength of conviction convinces. And it can hardly avoid one-sidedness and narrowness. Ferrara carried the flag of economic theory over an arid stretch of ground, keeping it alive, inculcating interest in it as only ardor can, stimulating his audiences, preparing the ground for better things to come. This was his achievement and it was great indeed. But his own exploits in the realm of theoretical analysis were, all the compliments of later writers and all efforts at favorable interpretation notwithstanding, distinctly unsuccessful. He saw clearly enough that economic phenomena and problems form a coherent set and that it is the theory of value which unifies them. But as the principle of this theory of value he adopted Cost of Reproduction in terms of labor, a principle that can be made general only by the most desperate twists of logic and, in any case, tells us little more than the old cost-of-production principle does if properly stated. There would be no point in singling out for criticism examples of impossible pieces of reasoning. Let us rather admire the strategist who won victories with such defective equipment and add that both his learned discussions of older authors and his pieces on banks, government fiat money, and other subjects contain many valuable things. His most important work, the *Esame storico-critico di economisti e dottrine economiche del secolo* XVIII *e prima metà del* XIX (1889-90) has been mentioned above. For a much more favorable appraisal, see Professor G. H. Bousquet's brilliant sketch, 'Un grand économiste Italien, Francesco Ferrara,' *Revue d'histoire économique et sociale*, vol. XIV, 1926, and also the introduction and notes to Ferrara's *Oeuvres économiques choisies* (ed. by G. H. Bousquet and J. Crisafulli, 1938).

7. United States

For the preceding period, we found that the small economic literature of the United States did not quite deserve the low opinion that a majority of American economists seem to entertain about it. For the period under survey, however, the opinion that Dunbar expressed in 1876, namely, that American literature had contributed 'nothing towards developing the theory of political economy'[1] has not been invalidated by the information made available by more recent research. It is indeed not true if we take account of problems raised, suggestions made, and factual work done, but it is true if we emphasize the word theory. Since this is the opinion prevailing in the profession, our account can be brief. Before presenting it, I wish to ask the question why that should have been so.

Minds that are unfamiliar with the sociology of scientific effort take it for granted that analysis follows the practical problem or, to put it differently, that it is induced by the needs of life. But in this case there were plenty of practical problems and they were eagerly discussed, sometimes with a degree of passion that was quite out of proportion to their importance. Nevertheless, we find hardly more than traces of an impulse to develop analytic tools for dealing with them. Moreover, there was plenty of demand for economic teaching—the quantity demanded was much greater than was the supply of competent teachers—which called forth courses and textbooks in response. One would think that giving a course or writing a textbook would induce a man to do at least a little thinking for himself, and that it would be difficult for a man to do either without asking himself when reviewing his derivative material: 'Could I not do better than this?' But evidently this is not so: the demand for courses and textbooks produced courses and textbooks and not much else. Does this not show that there is something to one of the theses of this book, namely, that need is not the necessary and sufficient condition of analytic advance and that demand for teaching produces teaching and not necessarily scientific achievement? The solution of the riddle seems simple, however. We have it as soon as we observe that absence of creative research was not peculiar to American economics of that period. We find the same state of things elsewhere, for example, in the fields of mathematics and theoretical physics where there is nothing to record until we reach the lonely peak that was Willard Gibbs—although there was no lack of technological problems, some of which, moreover, were solved with striking success. This suggests a common cause, and I do not see how we can avoid finding it in the conditions of the country and the aptitudes of her men: the task of exploiting the possibilities of the natural environment—which, given the social structure, presented itself in the form of unparalleled opportunities for business enterprise—both *absorbed* the creative talent of the country and *drew* to it talent of this type. Circles that did cultivate intellect and scholarship were quantitatively unimportant and sterile in scientific initiative. This, I believe, agrees with what Dunbar meant to convey, although he expressed himself in a manner that invites objection.[2]

---

[1] C. F. Dunbar (1830-1900), 'Economic Science in America, 1776-1876,' *North American Review*, 1876, reprinted in his *Economic Essays* (1904). For more information that I am going to present, the reader is referred to E. R. A. Seligman, 'Economics in the United States,' two articles that are combined into a chapter of his *Essays in Economics* (1925); F. A. Fetter, 'The Early History of Political Economy in the United States,' *Proceedings of the American Philosophical Society*, 1943. Among other American publications on the subject, I wish to mention particularly J. R. Turner, *The Ricardian Rent Theory in Early American Economics* (1921); and the useful bibliographies in M. J. L. O'Connor, *Origins of Academic Economics in the United States* (1944). The most important non American contribution seems to me to be E. Teilhac, *Pioneers of American Economic Thought in the Nineteenth Century* (trans. from the French by E. A. J. Johnson, 1936), a scholarly book that I feel all the more bound to recommend because its approach so completely differs from mine. [Had J. A. S. completed his History, he would have added Joseph H. Dorfman's *Economic Mind in American Civilization*, of which the first two vols. (1946) cover the period 1606-1865, and the third vol. (1949) the period 1865-1918.]

But I have emphasized the word theory, and what I meant by it was analytic apparatus. No such emphasis is needed in the cases of any of the textbooks I know, for they were commonplace, and worse, in any and every respect. Teaching fed mainly on McCulloch and Say, and where home-grown texts were used, it was McCulloch and Say again, except for some contributions of the Carey school.[3] But as regards the most significant figure in that period's

---

[2] Professor F. A. Fetter (op. cit., preceding footnote) has in fact objected to an explanation by 'environment' (rightly, of course, because the word itself explains nothing) and replaced 'environment' by two other factors: 'false authority' (of the English 'classics') and interested partisanship 'which blocks the path to disinterested scientific effort.' But the first of these factors needs to be explained in turn: for the hold of authority, false or not, is not a matter of course; the creative mind does not submit to authority; and, following this line, we are led back to the environment that either does not contain scientific talent or else absorbs it into other pursuits. As regards the partisan spirit, it was surely not absent in England, where economic analysis did flourish all the same. Nor does it in itself interfere with scientific effort. Finally, with great respect for Professor Fetter's high authority, I beg leave to remark that professors are not exempt from bias and that I sense some in the attitude of many excellent men to the nationalist school: surely, another interpretation may be put on the protectionist views of American economists of that and later times than subservience to either pecuniary interests or prejudice.

[3] On Say's success in the United States and also on his influence upon Carey, see Teilhac, op. cit.; the Prinsep translation of Say's *Traité* was first published in 1821. An American edition of McCulloch was published by J. McVickar, the first incumbent of the chair of political economy at Columbia. Destutt de Tracy was introduced to the American public, by no less a personage than Jefferson, in 1817. Of the home-grown products, the Rev. Francis Wayland's *Elements of Political Economy* (1837) was, I believe, the most successful. Having heard and read a number of scathing comments about it, I experienced something like agreeable surprise when I read it.

American economics, Carey,[4] that restrictive emphasis upon theory is very much needed. For he lacked creativeness only in that respect. And his case points an interesting moral about what technical deficiency may do to a man's reputation in the long run:[5] Carey's name has no doubt suffered much more from political animosity than from that deficiency; but nobody could have treated him with contempt had he stated his case with tolerable competence.

Carey's idea of the fundamental unity of all science—a sort of generalized Comtism—was not the idea of a man whose intellectual life is enclosed by tariff walls. The man who propounded once more the fundamental sameness of scientific law in all departments of knowledge was no doubt wrong; but there was an element of greatness in his errors. And the man who could conceive of the United States as a world unto itself, with all this implies economically, morally, culturally, had no doubt the gift of grand vision in the same sense as had List. In the light of this vision, his protectionism and his 'harmony' of agricultural, manufacturing, and commercial interests—his conception of a 'balanced' economy—acquire a new significance and one that is completely overlooked by all those who saw nothing in him but a mouthpiece of the business class. We need not like that protectionism and we need not like Carey's whole vision. In particular, we may feel that the United States would be a happier place and would have attained a higher cultural level by now if a larger part of the country's energies had gone into other than business pursuits and if, in consequence, her industrial development had been slower. This, however, is a matter of personal evaluation and does not excuse us from recognizing that Carey's was a great vision and that, in most respects, this vision expressed adequately both the situation and the spirit of the country. Moreover, we cannot excuse ourselves from recognizing that this vision

---

[4] For a list of his more important followers, see F. A. Fetter, op. cit. p. 56n. They—and presumably others—formed a school in our sense and also had personal contact with the Master, which was how they referred to him. The school was called and also called itself 'nationalist,' but it should be observed that this term entirely lacked the connotation of aggressiveness it has today.

[5] Henry C. Carey's (1793-1879) economic opinions were in part conditioned by those of his father, Mathew, who already felt himself to be the leader of a 'nationalist school.' Of the son's works, those that are most important for us are: *Essay on the Rate of Wages* . . . (1835; this first economic piece of his already displays his characteristic weakness on the side of analysis); *Principles of Political Economy* (1837-40); *The Past, the Present, and the Future* (1848); *The Harmony of Interests, Agricultural, Manufacturing, and Commercial* (1851); *Principles of Social Science* (1858-9); and *Unity of Law* (1872). This list neglects his writings on money and credit and several other things. The next to the last item is the one read and suffices for those who do not wish to make a thorough-going study of Carey. We need not go into the Carey literature beyond mentioning again his German admirer, Dühring. J. S. Mill described his *Principles of Social Science* as the 'worst book on political economy I ever toiled through' (G. O'Brien, 'J. S. Mill and J. E. Cairnes,' *Economica*, November 1943, p. 274) and said that he never met with 'such an apparatus of facts and reasonings in which the facts were so untrustworthy and the interpretations of facts so perverse and absurd' (ibid. p. 280).

was independent of its deplorable analytic implementation and capable of being implemented more satisfactorily. This, however, is precisely what Carey's critics refused to recognize. Most of them were more or less well-trained economists. They had no difficulty in showing that Carey's theory was no good at all. And, on the strength of this, they condemned his message without making it clear—and presumably without being aware of the fact—that the essentials of this message were beyond the range of theoretical analysis.

A comparison of Carey with the English free traders, on the one hand, and with List, on the other, will bring this out still more clearly. The English free traders and List also argued from a comprehensive social and political vision that we may or may not accept; both, moreover, argued from their respective national standpoints; both, finally, advocated policies that suited some group interests better than others. In all these respects there is no difference whatever between the cases of Carey and of either the English free traders or List except, of course, so far as our own preferences are concerned. But the English free traders implemented their visions and their politics analytically and with success—the theorem of comparative costs was a major contribution to our analytic apparatus. *This* is the reason why they may claim a place in the history of scientific analysis—not because of the advocacy of free trade per se. List made no original contribution to the analytic apparatus of economics. But he used pieces of the existing analytic apparatus judiciously and correctly. And this, too, spells *scientific* merit. Carey's case differs from both in that he made negative contributions to analysis. And my point is that this was entirely unnecessary either for the analytic implementation of the manner in which he saw American reality and problems or for the formulation of his policies, including protection, balanced economy, and all. If he lacked the gifts of the creative analyst, he could have used existing analytic tools as did List and, taking up his stand on United States data, could have argued that English views on many economic problems did not apply to American conditions and had to be modified by introducing other factual assumptions. Had he done so with a modicum of competence, his detractors would still have retained all the ammunition in the arsenal of politics, but he would have been all right on the scientific front.

He was, however, unable to distinguish the theoretical from the factual element in English free-trade teaching and distinguished neither from the element of political volition. He saw only the practical recommendations and naïvely thought that they followed from theoretical premisses which it was therefore incumbent upon him to demolish, root and branch.[6] Instead of saying simply that 'pressure of population' was, for the calculable future, evidently of no importance in the United States, he entered upon an infelicitous attempt to refute the Malthusian theory. Instead of saying simply that the most important practical—social and political—implications of the 'Ricardian' theory of rent did not apply in a new country, he argued ineptly (in the *Principles*

---

[6] It will be seen that he thus committed the same mistake that was committed by his free-trade critics.

of Social Science, 1858-9, not before) that this theory was totally invalid because cultivation did not typically proceed from richer to poorer soils, but from poorer to richer.[7] Instead of simply emphasizing the fact that under conditions of rapid development, rising cost curves are incessantly shifting downward so that the Ricardian theorem that equates prices to the cost of the 'least favored' producer loses much of its practical importance, he discussed decreasing and increasing costs as if they embodied conflicting propositions about the same phenomenon. And in his highest flight, his theory of value, he blundered so catastrophically as to crush its one good point. This theory is a labor-quantity theory that contains the improvement that it is not the labor quantity actually invested in a commodity but the labor quantity necessary for reproducing it that determines its value.[8] He observed that this quantity falls rapidly in the course of technological progress. And from this he inferred that labor's relative share must increase in the course of technological progress—which, besides being actually false, does not follow from the logic of his argument. In this case, it is particularly clear that what he strove to express was by no means wholly wrong: a competent theorist could have worked it up into a valuable contribution; but he made it read wholly wrong because he was unable to find for it the correct expression. There is no need to go on. But one interesting question remains. Plenty of people admired Carey's diagnosis of American reality and shared his views on economic policy and his enthusiasms. A prize, in terms of success and reputation, awaited the man who could have weeded the errors from his volumes and put his system into a defensible shape. Moreover, this prize was not hidden—and there were followers for whom it would have been the most natural thing in the world to pick it up. Why did nobody try? Well, opportunity is only a necessary and not a sufficient condition for a great performance. It does not of itself produce the man capable of using it. And the brains that could have done the job were producing boots.

However, though nobody undertook the task in all its wide dimensions and though nobody undertook it effectively even in any of its parts, a number of writers did attempt it within a narrower compass and with inadequate force. These writers were not all of them forerunners or followers of Carey. Nor did they form any school in our sense of the term. But, reasoning as they did on the same data and problems and, to some extent, in the same spirit, they produced publications that have some affinity with Carey's as well as a certain family likeness between one another. Some of them described their economics as American Political Economy, and this phrase may be fittingly applied to all of them. They were all more or less protectionist. But the family likeness extends beyond this feature to others that are more relevant to us, namely, to the features of their modest analytic apparatus that was for the most part derived, by either acceptance or criticism, from A. Smith. There was, however, no first-rate man among them, and they made next to nothing of the great opportunity before them. Nor did they attain any dominant position. Accordingly, they do not dominate the following list, which offers, I believe, a fairly representative sample of that period's United States economists: Raymond, Everett, Tucker, Bowen, and Amasa Walker.[9] If we like, we can include in American performances also List's early book, which was a typical product of the American environment, and possibly also John Rae's great work, which was discussed in the first section of this chapter. Of course, this excludes writings on money and banking and the still more important factual work that was done by United States economists.

---

[7] The reader will realize, of course, that it is not his assertion about historical fact that condemns Carey as a thinker—for it is possible to put up a case for his theory that, historically, poorer soils are cultivated before richer ones: this may occur for more reasons than one—but his belief that this assertion, true or false, is relevant to the Ricardian theory.

[8] This theory, which Carey elaborated in his *Principles of Political Economy* (1837-40), differs essentially from Ferrara's theory of cost of reproduction.

8. Factual Work

In the course of the review above, we have repeatedly had occasion to commend the admirable factual work done by men who are usually classed as 'general economists' or even as theorists only but who are not fully understood unless the proportion of their time and energy that went into the hunt for, and the presentation of, facts is taken into account. Let us glance once more at a selection of relevant names, great and small: Blanqui, Chalmers, Chevalier, Garnier, Gioja, Malthus, Messedaglia, McCulloch, Mangoldt, James Mill (*History of India*), Roscher, Senior, Storch, and Thünen. This list, which could easily be lengthened, suffices to show that the economics of the period under survey, taken as a whole, was anything but the speculative thing it is sometimes made out to be and that the opinion—the source of much pointless controversy—that the economics profession then neglected factual research is utterly unfounded. The opposite opinion would in fact be nearer to the truth:

---

[9] For a more favorable appraisal than is implied in my way of mentioning Daniel Raymond (1786-1849), who wrote *Thoughts on Political Economy* (1820; 2nd ed., entitled *Elements of Political Economy*, 1823) see Teilhac, op. cit. The difference is largely accounted for by Professor Teilhac's emphasis upon the economic-thought aspect of Raymond's work, which is indeed more interesting than is his analysis. The presence of analytic effort must, however, be recognized. He produced a theory of capital (in the intermediate goods sense) that, considering its date, is not without merit. On A. H. Everett's chief performance, see below, ch. 6. George Tucker (1775-1861) wrote, among other things, *Laws of Wages, Profits, and Rent Investigated* (1837); for other contributions of this not insignificant economist, see below, sec. 8b and ch. 7, sec. 3. Francis Bowen's *American Political Economy* (1870; first publ. as *Principles of Political Economy applied to the Condition, the Resources, and the Institutions of the American People*, 1856) stands here only because of its title. Amasa Walker's (1799-1875; father of Francis A. Walker) *Science of Wealth* (1866) must be mentioned as a representative performance of the 'non-American' line of United States economics. Perusal of the book will give the reader a good idea of what this economics then had to offer. For the rest, the reader finds all he needs for further study in Seligman, op. cit.

many of the shortcomings of the 'classic' analytic apparatus find their most natural explanation on the hypothesis that the amount of work bestowed upon it was inadequate, whereas it is not possible for us to level the analogous criticism at the period's factual work, especially if we include, as we must, the work of economic historians and of the students of legal institutions that we have sampled already in the preceding chapter. This section will present additional examples of important types of factual work and thus help to round off our picture and to establish our thesis that the 'classic' period fully maintained the tradition of factual research that, as we know, harks back to the sixteenth century.

[(a) *Tooke's* History of Prices.] Of particular interest to us is the type of analysis that combines presentation and explanation of facts in such a way that the two cease to be distinct tasks and mutually condition one another at every step: the type of analysis that arrives at its results by means of discussing individual situations. We must be content to notice the peak achievement of this genus, the *History of Prices and of the State of the Circulation from* 1792 *to* 1856 by Tooke and Newmarch.[1] A better title would have been: Analysis of England's Economic Processes from 1792 to 1856, with Special Reference to the Condition of the Currency and of Credit. Jevons called it 'unique,' and so it is. Never before or after has that method been used on an equally large scale, or, so far as influence upon purely theoretical research is concerned, with similar effect. Whether the authors handled it as well as they might have done is another question. I am not alluding to the fact that, of course, they argued for one policy and, still more obviously, against another: this does not impair the value of either their facts or their reasoning, both of which may be appreciated by any opponent of their views concerning desirabilities. Nor am I alluding to the discursiveness and repetitiveness of their work: in 'realistic' theory of this type neither is without its function—the method is essentially one of 'thrashing out' things, and this cannot be done with Ricardian brevity. I am alluding to more fundamental defects of which no trained reader of these volumes can fail to become aware very quickly. Both authors were no doubt deficient in command of economic theory. Tooke was in addition a somewhat 'woolly' thinker—who often impaired his case by missing the opponent's point. And this told. Not only did his arguments sometimes call forth derogatory comment, that was quite justified as far as it went; but also, his authority, great as it was in his day and as it remained for the rest of the century, was never what it might have been had there been more theoretical edge to his thought. The work is nevertheless a classic and an example to follow. But it seems to cry out for rewriting by a better-trained or else a more adroit hand.

---

[1] Thomas Tooke (1774-1858) was the author of all six volumes, if the term 'author' is taken in the sense of the Latin *auctor*. But only the first four volumes (1st and 2nd, 1838; 3rd, 1840; 4th, 1848) were substantially his work, the collaborators playing the role of research assistants. The last two volumes (1857) were mainly the work of William Newmarch (1820-82), who, though greatly influenced by Tooke, holds his place in his own right. Newmarch, besides being one of the more important critics of Peel's Act and the doctrines of the 'currency school,' was a leading member of the Royal Statistical Society, and the originator of the *Economist* index number and the same journal's 'Annual Commercial History.' As regards index numbers (which, by the way, were not used in the *History of Prices*, a striking example of economists' resistance to new methods), he was not particularly original, but the 'Commercial History' is an interesting model for an interesting type of work. Economists are even today not fully alive to its scientific importance and to the methodological questions it raises, and have hardly succeeded in bringing modern theory to bear upon it or in otherwise improving upon Newmarch's performance. The *History of Prices* has been republished (1928), ed. by Sir T. E. Gregory with an introduction that fully discusses its nature and origin, and should be carefully perused by the reader. This reference is to replace a survey of the various writings of Tooke's that paved the way toward the *History*.

[(b) *Collection and Interpretation of Statistical Materials.*] Though anything but a novelty, work of the kind of which Tooke's and Newmarch's is an outstanding instance was in that period powerfully propelled by the opening up of new sources of statistical figures. Those were the times when governments began to establish statistical bureaus and commissions; when the first attempts were made at international co-operation (the first international statistical congress met in 1853); when statistical societies emerged almost everywhere—in England, for instance, several were founded in the 1830's, of which the Statistical Society of London (1834) was presently chartered as the Royal Statistical Society.[2] To a great extent the compilation, from the raw material provided by the official bureaus, of presentable statistical records remained the task of individual investigators, as it had been in the preceding period, especially but not exclusively of the men who by virtue of their official position were able to command the requisite assistance. But these investigators were no mere diggers. They did not confine themselves to marshalling data and to developing estimates: many of them also offered interpretations. And so we find, flowing from this source, another stream of work that differed indeed from Tooke's and Newmarch's in that it started from the statistical material instead of from the economic problem and, in consequence, emphasized the statistical information per se more than had Tooke and Newmarch. But, though sometimes only as a by-product, they turned out analytic work as well.

Attention has been called, in our survey of pre-Smithian times, to what may be described as analyses of the economic state of a country. In the period under discussion, this line of research produced a number of performances for which Colquhoun's, Porter's, and Tucker's will serve as examples.[3] They—

---

[2] The American Statistical Association was organized in 1838.

[3] Of Patrick Colquhoun's (1745-1820) many writings, only two need be mentioned, his *Treatise on the Population, Wealth, Power, and Resources of the British Empire* . . . (1814), unintelligently sneered at by McCulloch, and the anonymously published *Considerations on the Means of affording Profitable Employment to the Redundant Population of Great Britain and Ireland* (1818). The first is particularly important, not so much because of its estimates of national wealth, but because of the economic reasoning, however primitive, which is offered in explanation of the facts presented, and of the

and others of the same type—no doubt suffer from the fact that their authors did not know how to use economic theory as a tool of factual analysis; but as far as this goes they are in the same boat with modern publications of this kind. Other types of that period's statistical economics will be represented by the names of McCulloch, Baxter, Dieterici, Villermé, Le Play, and Wells.

McCulloch's (see sec. 2 above) most significant statistical work, his *Dictionary, Practical, Theoretical, and Historical of Commerce and Commercial Navigation*, 1832—a heroic labor—is in spite of its dictionary form, a treatise in which facts and analysis intertwine very effectively. This was the kind of thing at which he was really good—the man should in fact not be judged by his *Principles* alone.

Robert D. Baxter (1827-75) was an economist of major importance. His careful and competent handling of his figures, and his much quoted estimates (of national income and wealth), admirable though they are, constitute the least important of his services to economic analysis. Of much greater interest for us are his bold ventures into the statistical theory of the benefits that accrue to the public from railroads and of the pressure and incidence of taxation (for which purpose he also collected family budgets). These studies are not faultless, mainly because he was weak on the pure theory side, but the mere fact that he made a serious attempt to answer numerically such questions as how the burden of rates divides itself between landlord and tenant should secure for him a place in the history of econometrics. I want to refer especially to: *The Budget and the Income Tax* (1860); *Results of Railway Extension* (1866); *National Income: the United Kingdom* (1868); *The Taxation of the United Kingdom* (1869). *In Memoriam* by his widow is well worth reading.

Karl F. W. Dieterici (1790-1859) was a professor of Political Economy (*Staatswissenschaft*) and director of the Prussian Statistical Bureau in Berlin. *Statistische Übersicht der wichtigsten Gegenstände des Verkehrs und Verbrauchs im preussischen Staate und im deutschen Zollverbande* . . . (1838-57). Also important: *Der Volkswohlstand im preussischen Staate* . . . (1846) and *Über preussische Zustände, über*

---

attempt to state and to solve problems—to paraphrase factually, as it were, the more popular doctrines of the times.

On a larger scale, and with greater success, this was also done by George R. Porter, a civil servant and for some time chief of the statistical department of the Board of Trade. His *Progress of the Nation in its Various Social and Economical Relations, from the beginning of the Nineteenth Century to the Present Time* (1836-43) has received deserved credit as the standard record of English economic development during the first half of the nineteenth century, i.e. as a source book of economic facts and figures. As such it has been remodeled—very freely indeed—and continued by Mr. F. W. Hirst and his associates (1912). But this is not what matters for us. The relevant point is that the work, as originally planned and executed, is really a treatise of general economics, dealing successively with population, production, interchange, public finance, consumption, accumulation, moral progress, and colonies in a manner not entirely dissimilar to Mill's *Principles*, of which, in a sense, it ought to be considered as the companion volume: in particular neither Mill's free trade nor Porter's free trade is complete without the other.

George Tucker has been mentioned already and will have to be mentioned again. The work of his that is relevant here is: *Progress of the United States in Population and Wealth in Fifty Years* (1843; 2nd ed., 1855). It is mainly a study in U.S. demography. For us, however, more important is the fact that it is also a study in economic analysis.

Arbeit und Kapital (1848). His delightful serenity in matters of 'method' deserves to be recorded. His lecture *De via et ratione oeconomiam politicam docendi* (1835), though stressing quite reasonably the fundamental importance of the historical aspects of the economic process, arrives at the result which might be said to sum up, by anticipation, all that ever came of the methodological squabble of a century: *et mere philosophando et mere experiendo erratur.* And he showed his good sense by extolling Ricardo's attention to facts. Though he never embarked upon a venture as comprehensive as Porter's, his neat and trustworthy publications of the results of the statistical bureau he directed are glorified by his grasp of the needs of scientific economics that enabled him to pick out fertile projects. Thus, his statistics of consumption continue to this day to render assistance to analysis.[4]

The work that justifies the inclusion in our sketch of the name of Louis R. Villermé (1782-1863), who was not exclusively, or even primarily an economist, is his investigation, undertaken as a research project (quite as such things are done today) under the Académie des Sciences Morales et Politiques, into the conditions of labor in several French manufacturing industries: *Tableau de l'état physique et moral des ouvriers employés dans les manufactures de coton, de laine, et de soie* (1840). His recommendations (protection to children) do not interest us here. The work is important as an outstanding instance of a large class, in which method of procedure has hardly made any progress at all since that time.

P. G. Frédéric Le Play (1806-82), mathematician and mining engineer by training and professor of metallurgy by vocation, figures here and not in the next period although some of the publications and activities that made his international fame belong to the latter. The Société Internationale des Études Pratiques d'Économie Sociale, which was founded by Le Play in 1856, started the publication of a fortnightly review, *Réforme sociale*, in 1881. The work that is relevant to our purpose was done during the period under discussion: *Les Ouvriers européens* (1st ed., 1855; 2nd ed., 1877-9). He was not a technical economist and heartily despised the misunderstood bits of economics he knew. Nevertheless, he deserves a place in the history of economic analysis because of his method of studying family budgets that may some day help to bring into existence a theory of consumption worthy of the name. It consists in an immensely painstaking investigation of a limited number of individual cases, each considered as intensively as possible, in the whole setting of its social, moral, and cultural conditions. We cannot go into the program of social betterment that is associated with the name of that great man. But he formed a school that is associated with that program and continues work along that line.

As has been mentioned already, statistical economics flourished in the United States, and from the famous Hamilton *Report on Manufactures* (1791) to the end of the period we observe an ever-broadening stream of such publications. However, we shall be content to add another illustrative instance, namely, the earlier work of D. A. Wells—his later and much better-known work belongs to the next period.[5] He turned to economics in his early middle age, attracted by his interest in the practical questions of his day and country, and our analytic apparatus owes nothing to him. Yet he was a significant economist whose works repay study even today. He was a master of the art of making the most of imperfect material.[6] Moreover, his sound and conscientious mind enabled him to represent the elements of a situation in their right perspective without precisely knowing why: his was that sound practical judgment in which many of the best theorists are woefully deficient and which was to show up to still greater effect in some of his later publications.

---

[4] Among other things, they established the fundamental fact that the consumption of the masses may fall in *cyclical* upswings (that it may fall in prolonged spells of inflation is of course common knowledge).

[5] David A. Wells (1828-98) was a geologist and chemist who had published a successful textbook in each of these subjects before he took to economics and the civil service during the Civil War. The two publications that should be mentioned here

Of course, all that I have been able to present in this section is a scatter of instances that in addition may not have been the best to choose. Thus, barring what is implied in mentioning Tooke and Newmarch and also Senior, I have entirely neglected all the *scientific* economics to be found in English official reports. It is hoped, however, that even these bits of information will help the reader to form a correct idea of the scientific situation of that period. But the question must, I suppose, arise in his mind how, under the circumstances described, it was *possible* for even the most unfair of critics to speak of undue preponderance of 'theoretical speculation.' The only answer I have to offer is this. Criticism of scientific economics comes to a great extent from ignorant outsiders, and these ignorant outsiders include many individuals who call themselves economists. This fact alone makes it understandable that criticism mistook the significance of a feature of that period's economic work that we have noticed before. Economics then gained the status of an established field. This meant, among other things, greater specialization not only of individuals but also of publications and the emergence of purely theoretical treatises. It is hardly possible to overlook the factual complement in the *Wealth of Nations*—though some critics seem to have accomplished even this feat—and it is still less possible to overlook the factual work in Vauban's *Dixme royale*. But if an economist, such as Senior, chooses to deal with the analytic apparatus of economics separately, then it is much easier to overlook his factual work—especially if it be hidden in commission reports—and thus, comparing the *Outline* with the *Wealth* (which is of course absurd), to arrive at the discovery that there is a methodological gulf between the two and that Senior was indulging in pure speculation whereas A. Smith was keeping his eyes upon historical fact.

[(c) *Development of Statistical Methods.*] The groups of workers in any department of scientific knowledge should not perhaps be compared to the corps of an army. For the latter, at least in principle, move according to some plan, whereas the scientific groups are essentially unco-ordinated: one group

---

are: the famous *Our Burden and our Strength* (1864) and his *Reports of the Special Commissioner of the Revenue* (1866-9).

[6] Professor Kuznets has told me that Wells's estimates of national income are deserving of confidence which, considering the data at his disposal, represents an even greater feat than Baxter's, who had at least income-tax data to go on.

rushes on, the others lag behind, and each fails to give support to the others or to avail itself of the possible support it could derive from them. The progress in statistical method illustrates this. We have already noticed that there was considerable advance on the probability front. We should add to this the Gaussian law of error and the method of least squares, achievements that meant an important addition to the economist's box of tools. However, nothing to speak of came of this opportunity during this period in which, on the contrary, the statistician's pure theory and the economist's pure theory were almost completely divorced—to remain divorced until our own day. I wonder if I can create in my reader's mind the proper feeling of surprise at this. Let us for this purpose transfer ourselves into a better world and, from this better world, look at the situation of economics. We then behold a field in a large part of which reasoning is essentially and inevitably quantitative—surely all economists would have acquired a saving knowledge of mathematics. But even if they failed to see the necessity of doing this in order to improve their pure theory, would they not surely do so in order to improve their handling of statistical figures, to the importance of which, as we have just seen, they were fully alive? They would be on the lookout for new tools of statistical research and, of course, rush to use them if they were proffered, as they were being proffered, from outside. And we should expect the author of the period's leading treatise, J. S. Mill, laboring in the sweat of his brow, to acquire and to teach command of those tools. Observe that, with a profession intellectually alive and moderately conscious of the scientist's duties, there would have been nothing impossible in all this. But as a matter of fact, if we let our glance shift back to the real world, we see nothing of all this until about a century later, and even then all we see is a painful struggle to realize it. What we do see, for the period under discussion, is ignorance born of intellectual inertness or else, which comes to much the same thing, preoccupation with the practical problems of the day that life itself solved without needing any assistance. It was not quite so in demography or what is usually understood by social statistics. This is our only opportunity to mention the name of Quetelet.

Adolph Quetelet's (1796-1874) importance for our subject is small—I know of no economist of that period whose *economics* shows any traces of his influence. He was a mathematician and astronomer, and entered the field of social statistics by the door of probability. Here, so far as I can see, his merit is confined to meritorious propaganda: there is nothing original in his *Lettres à S. A. R. le duc régnant de Saxe-Coburg-Gotha sur la théorie des probabilités, appliquée aux sciences morales et politiques* (1846). But he joined the brilliant band of statistical administrators who during that period led and inspired the new statistical bureaus and, with indefatigable energy, did much to improve methods and projects and especially to promote international cooperation.

He was much more than that implies, however. His vigorous and original investigations into the distribution of human characteristics mark a step in advance that had never to be retraced and, as an example to follow, had eventually also some importance for economics. But he took another step that, after a brief success, had to be retraced: he plunged into a philosophy of a sort of statistical determinism by conceiving the theory that those investigations were revealing a stable type of average man whose properties linked up with simple general 'causes,' deviations being of the nature of errors of observation in the Gaussian sense. He thus hoped to reduce, on a statistical basis, the methodology of the social to that of the physical sciences. The development of thought in this matter went wholly against this theory, and many serious workers came to consider it, perhaps more than is justified, as a mere freak. His merits concerning anthropometry are of course not affected thereby. See especially his *Sur l'homme* . . . (1835; English trans., 1842), later expanded into his *Physique sociale* . . . (1869) and, for criticisms, G. F. Knapp, 'Quetelet als Theoretiker,' and several other notes, *Jahrbücher für Nationalökonomie und Statistik* (1871-2) and Maurice Halbwachs, *La théorie de l'homme moyen* (1912).

Economists even failed to avail themselves of the most primitive devices for presenting figures. All the more necessary is it to notice the fact that at least simple charting—line, bar, circle, and pie graphs—had been introduced into economics right at the beginning of the period by Playfair.[7] Moreover, there is no excuse for the hesitation with which fact-presenting economists took to the use of price index numbers or theoretical economists to the task of providing a theory for them. We have seen that the idea had emerged before A. Smith. A great step toward full realization of the importance of the method was made in 1798, when Sir George Shuckburgh Evelyn presented a paper to the Royal Society in which, with apologies for treating a subject so much below the dignity of that august body, he used an index number—of a primitive kind no doubt but which was superior to Carli's—for measuring the 'depreciation of money.'[8] Lowe[9] added nothing to the idea of a 'tabular standard' beyond Evelyn's, but he improved the technique and recommended the use of index numbers for the purpose of 'lessening the injury from fluctuations and giving a uniform value [over time] to money income,' that is, of creating a stable unit of deferred payments—the idea that was to become so popular in the next period and still more so in the 1920's and 1930's. G. Poulett Scrope seems to have been the first to introduce the subject into a general treatise (1833).

---

[7] William Playfair, brother of the physicist, John Playfair, to whom he gave credit for having suggested his graphical methods, was a man of varied experience in business and economic journalism. He first introduced those methods in his *Commercial and Political Atlas* (1786), which contained 44 charts and was translated into French. His most telling graph, however, was used to illustrate his argument in *A Letter on our Agricultural Distresses*; it displays the course of the price of wheat and of wages over 250 years. See Funkhouser and Walker, 'Playfair and his Charts,' *Economic History*, February 1935, with illustrations. I owe my acquaintance with Playfair's work to this article, and know only the two publications mentioned. For others, see the bibliographical note appended to the article.

[8] *Philosophical Transactions*, 1798, Part I. Arthur Young (*Enquiry into the Progressive Value of Money in England*, 1812) was the next to follow him and the first to attack him.

[9] Joseph Lowe, *The Present State of England in regard to Agriculture, Trade and Finance* (1822), a book that seems to have met with some success and contains many interesting discussions, e.g. on population. The author is, however, very unfair to Evelyn's pioneering attempt.

CHAPTER 5

General Economics: A Cross Section

6. THE 'CLASSIC' CONCEPTION OF ECONOMIC DEVELOPMENT 570

1. J. S. MILL AND HIS *Principles*. FAWCETT AND CAIRNES

MILL'S *Principles* was not only the most successful treatise of the period under survey but also qualifies well for the role of the period's classic work *in our sense*. Having decided to choose it as headquarters from which to survey the general economics of that period, we had better begin by a preliminary glance at the man and the book.

John Stuart Mill (1806-73) was—John Stuart Mill. That is to say, he was one of the chief intellectual figures of the nineteenth century and is so familiar to every educated person that it might seem superfluous to add anything to what can be read in dozens of books. Moreover, most of what economists need to know about him has been admirably said by Sir W. J. Ashley in the introduction to his edition (1909) of the *Principles*, which I hope is in the hands of every student.[1] A few points must be touched upon all the same. Most of us have heard or read of the severe intellectual training to which James Mill, the father, subjected his son from early childhood and which, much more cruel and injurious than daily whippings would have been, accounts for that impression of stunted growth and lack of vital strength that comes to us from many passages in the imposing work of his life. Most of us, I suppose, also know that it was first a salary and then—after 1858—a pension from the East India Company which financed his needs (fairly comfortably), and that his duties, though not on the average very arduous, meant further injury to his thought: as has been pointed out already, not only interruption but also mere anticipation of possible interruption paralyzes creative research. Then, too, his unflagging interest in current issues caused additional interruption and loss of energy. This interest and the office combined account for the incessant hurry that all his writings display, even the one that is the most finished of all in a literary sense, the essay *On Liberty*. Finally, being all intellect and having been taught to despise any but intellectual interests—and of these all that do not come within the pale of utilitarianism, though he outgrew this part of his father's teaching as he did others—he never knew what life really is. He did create an intimate *foyer* for himself by his friendship and, later, marriage with Mrs. Taylor. But he intellectualized that too, and anyone who has an ear for the note of hysteria in the Preface to the essay *On Liberty* will need no other indications—to be gleaned, for example, from his *Autobiography*—in order to feel that he lacked many of the requisites, not indeed of the theorist but of the philosopher of social life.

---

[1] Attention is called particularly to the appendix of this edition, which puts, with substantive success, many items of Millian doctrine into their relation to contemporaneous, earlier, and even later thought, and should be carefully studied. For the rest, competent analyses of Mill's economic work are rarer than are competent appraisals of his work in philosophy and logic. But there is one that has been written by a master: Edgeworth's article—'Mill, John Stuart,' in *Palgrave's Dictionary*—on no account to be omitted. Moreover, E. Cannan's *Theories of Production and Distribution* (3rd ed., 1917), the most important individual reference for this and the next chapter, discusses Mill's economics very fully.

We behold the picture of the purebred laicist radical. But, unlike other laicist radicals, this one never allowed indoctrination to stifle criticism. With an honesty and internal freedom that cannot be too much admired, he took the critical axe to the foundations of his laicist and utilitarian religion—for this is what it was—and, still more important, he opened the doors of his mind to any message he was able to comprehend. He tried to get on terms with the ideas of Carlyle and Coleridge; [2] he studied Saint-Simonism and Comtism profoundly; by his critique he proved how seriously he took the question raised by the Hamiltonian philosophy; and, honestly wrestling with all this and much besides, he actually allowed himself to be drawn away from his early moorings. He was the opposite of a zealot. Not only the range of his interests but also, in a sense, the range of his comprehension was quite abnormally wide.

---

[2] In two articles contributed to the *London and Westminster Review* (1838 and 1840, reprinted in *Dissertations and Discussions*, vol. 1) J. S. Mill formulated his mature opinion on the contribution of Coleridge and his group to sociology and, by implication, on their influence upon himself. Perusal of these articles must, I think, enhance our respect for their author. Mill goes a long way toward accepting their criticism of eighteenth-century rationalism—and the 'interest philosophy of the Bentham School'—and shows himself quite open to their romanticist conception of history: in fact, I do not think that the man who wrote these articles—and the passages on James Mill's theory of government in the *Logic* (see above, ch. 3, sec. 5c)—can properly be called a utilitarian at all. But he understood technical economics too well to throw it overboard on that account. To critics who did not understand it equally well, this looked like hesitation and like endless shifting of standpoints. Actually, however, his views were, *in this respect*, perfectly consistent and, in addition, far ahead of his time.

But now I have to add a point that is extremely difficult to make and very liable to be misunderstood. You can travel far and wide and yet wear blinkers wherever you go. Mill's comprehension never went below certain layers—we have noticed this already when discussing his *Logic*—and his intellect never got over certain barriers. What was below these layers and beyond those barriers he put down as nonsense by means of the well-known trick of our subconscious apparatus of self-defense.

Of his three great works, the *Logic* (1843), the *Examination of Sir William Hamilton's Philosophy* (1865),[3] and the *Principles of Political Economy with Some of their Applications to Social Philosophy* (1848), only one is in our field. The list of his other writings[4] strengthens an impression that interests other than economics were dominant with him, since the list contains only one item that deals with questions of technical economics: *Essays on Some Unsettled Questions of Political Economy*, containing his freshest and most original contributions to economics. And in fact, if we claim him for our own, nevertheless, we must always remember in justice to the man that, after his late twenties, he never was a full-time (or even 'full leisure-time') economist except in 1845-7, when he wrote the *Principles*. As regards the influences that helped to shape his economics, those of his father and of Ricardo himself come first, of course. But I have said already, and have emphasized by my refusal to include J. S. Mill in Ricardo's school, that the economics of the *Principles* are no longer Ricardian. This is obscured by filial respect[5] and also, independently of this, by J. S. Mill's own belief that he was only qualifying Ricardian doctrine. But this belief was erroneous. His qualifications affect essentials of theory and, still more, of course, of social outlook. Ricardianism meant no doubt more to him than it did to Marshall. But Mill's and Marshall's cases are similar in that for reasons of their own, commendable or not, they stressed Ricardian influences unduly at the expense of others. From Marshall's *Principles*, Ricardianism can be removed without being missed at all. From Mill's *Principles*, it could be dropped without being missed very greatly. The influence that J. S. Mill failed to stress adequately was Say's. He did stress it in one point only, the Law of Markets. But it is present in Mill's theory of value and cost—which is essentially a compromise between Ricardo's and Say's, with all the emphasis put upon the Ricardian elements—that is to say, in the very heart of his theoretical structure. The other influence to which Mill submitted, semiconsciously and rather reluctantly, was that of Senior, who also receives explicit recognition in one point only—abstinence. There are many others, Malthus' and Rae's, for example, which Mill accepted consciously and hence recognized frankly—for he was scrupulously fair to others, always ready to give credit to them, and quite indifferent to any claims of his own. This fairness and this indifference are among the strongest and most lovable traits of his character and the remarks above on the influence of Say and Senior must not be interpreted to imply any aspersion or any doubt on this score.

---

[3] The *Logic* and *Hamilton's Philosophy* have been discussed above in ch. 3.

[4] Any work of reference will give this list. For us, the most important items, in addition to the three above, are: the *Autobiography* (1873; two new editions by J. J. Coss, 1924, and H. Laski, 1924); *Some Unsettled Questions* (publ. 1844; written about 1829 and 1830); *On Liberty* (1859); *Considerations on Representative Government* (1861); *Utilitarianism* (1863); and *Auguste Comte and Positivism* (1865).

[5] This no doubt commendable attitude of the son also obscures the nature of the influence of the father in other respects, e.g. in respect to associationist psychology. This influence may indeed be called dominant if we mean by influence the total effect of a man's teaching upon another man. But it is not dominant at all if we count as influence only effects that show in conformity of views. In many if not in most departments of thought, the son, though still reacting to his father's opinions, arrived at different, often opposite, standpoints. On one point noticed above, it is an enemy of James Mill's teaching that speaks to us from the pages of the son.

Mill's declared purpose in writing the *Principles* and the performance actually embodied in it fit like hand and glove. The original preface is worth reading. He might with little change have reprinted the preface to the *Logic*. Once more, the program was to untie knots and build bridges. There is no claim to novelty or originality—though several would have been justified. Mill simply explained that there had been no equally comprehensive treatise, especially none that paid so much attention to practical applications, since the publication of the *Wealth of Nations*. This, however, was obsolete, both as regards facts and as regards theory. So he would aim at the 'sufficiently useful achievement' of writing 'a work similar in its object and general conception to that of Adam Smith, but adapted to the more extended knowledge and improved ideas of the present age' which is 'the kind of contribution which Political Economy at present requires'—and exactly the kind of book he wrote. For a man of Mill's powers and standing, modesty could not have gone further. Two comments should be added.

First, there is a side to this admirable modesty that may perhaps be held responsible for a less admirable consequence. Had Mill conceived a less modest idea of his task, he might have produced an even better book. As it was, he took his task altogether too lightly: not Hercules himself could write a *Wealth of Nations* in eighteen months, which seems to have been the actual time invested. But, as we have had occasion to remark with respect to the *Logic*, Mill, however modest on his own behalf, was not at all modest on behalf of his time. 'This enlightened age' had solved all problems. And if you knew what its 'best thinkers' thought, you were in a position to answer all questions. I do not mean to repeat what I have previously said on Mill's attitude of speaking from the vantage ground of definitively established truth. But I mean to add that this attitude, besides being ridiculous, made for sterility and—yes—superficiality. There is too little attention to groundwork. There is too little thinking-things-through and much too much confidence that most of the necessary thinking had been done already. The Smith-Mill-Marshall line is clear enough. But the middle term is not on a par with the other two, owing to relative insufficiency of labor applied. What looks like so many tergiversations or what gives the impression, energetically voiced by Marx, that Mill never says a thing without also saying its opposite is in part due to this cause. But to a greater part it is due to Mill's judicial habit of mind that forced him to consider all aspects of each question. Also, it is due to something that is still more creditable. He was a man of strong preferences. But he also was incorruptibly honest. He would not twist either facts or arguments if he could help it. When the preferences—his social sympathies—did assert themselves all the same, he was not slow to apply the pruning knife. Hence many an inconclusive result, or even many a contradiction.

Second, Mill emphasized repeatedly, though not in his preface, that his *Principles* differed from other treatises in something he ascribed to his wife's influence, namely, in moral tone or atmosphere. There is, in fact, plenty of warm-hearted humanitarianism about the book and plenty of solicitude for the welfare of the laboring class. More important, however, is a cognate aspect: he restricted the domain of inexorable law to the physical necessities to which production is subject and emphasized for all the rest, all institutions in particular, that they are man-made, changeable, malleable, and 'progressive.' There was for him no invariable natural order of things social, and economic necessity meant to him largely necessity in regard to a given state of the changing institutional frame. However much he glorified his age in other respects, the actual state of society he beheld he did not consider as either ideal or permanent. Book IV, Chapter 7 of the *Principles* and many other passages, even some of those that criticize the utopian socialism of his time, are conclusive on this point and also as regards the direction that he expected social development to take. Though repeatedly changing his position in details, he was, from about his middle twenties on, an evolutionary socialist of associationist complexion. For a history of analysis, this fact is important only in as much as it refutes the absurd indictment that 'classic' economists believed in the capitalist order as the last and highest wisdom that was bound to persist in *secula seculorum*. If it be replied that Mill was a solitary exception, the answer is that this is not true, but that, even if it were true, this exception was responsible for the most successful and most influential treatise of that age. For the sociologist of capitalism, this fact is still more interesting: nothing can be more revealing of the character of bourgeois civilization—more indicative, that is, of its genuine freedom and also of its political weakness—than that the book to which the bourgeoisie accorded such a reception carried a socialist message and was written by a man palpably out of sympathy with the scheme of values of the industrial bourgeoisie.

J. S. Mill was exactly what is meant by an evolutionary socialist. His attitude toward socialism went through a steady development, the traces of which are but imperfectly discernible in the successive editions of the *Principles*. Moreover, the three articles on socialism which Miss Helen Taylor published in the *Fortnightly Review* (1879) after Mill's death are perhaps more misleading than helpful: they were written in or about 1869 as exploratory sketches for a book on socialism which Mill then intended to write, and contain little more than critical appraisals of the French and English socialist literature prior to 1869 and of current socialist slogans; the book presumably would have contained a positive complement that might have reversed the impression the reader of these sketches is likely to get. However, neglecting all minor points, we may with some confidence describe Mill's attitude to socialism as follows. Emotionally, socialism always appealed to him. He had little taste for the society he lived in and plenty of sympathy with the laboring masses. As soon as he had gained intellectual independence, he readily opened his mind to the socialist—mainly French—ideas of his time. But, being a trained economist and thoroughly practical-minded, he could hardly fail to perceive the weaknesses of what a little later was labeled Utopian Socialism by Marx. Reluctantly and with a partial exception in favor of Saint-Simonism, he therefore arrived at the conclusion that those plans were but beautiful dreams. This was the first stage. On the face of it, a completely negative attitude to socialism—coupled with thoroughgoing radicalism in some respects, for example, with respect to property in land —might be considered compatible with what he wrote in the first edition of his *Principles*. But there is no reason to doubt his statement in the preface to the third edition (1852) which was to the effect that he never intended to 'condemn' socialism 'regarded as an ultimate result of human progress,' and that his objections merely rested on 'the unprepared state of mankind.' The alterations and emendations in the text went, however, further than this suggests (see in particular the new second paragraph of ch. 7 of Book IV) and really amount to *explicit* recognition of socialism as the Ultimate Goal. This marks a second stage. And there was a third: on the one hand, he came to believe that 'progress' was accelerating wonderfully and that this 'ultimate end' was coming rapidly within view; on the other hand, he came to believe that capitalism was near to having done its work so that purely economic objections were losing part of their force. At the same time he always stoutly denied the presence of any tendency in the capitalist system to deteriorate the condition of the working class or to reduce its relative or absolute share in the social product; and not less stoutly he refused to entertain the idea of transition by revolution, basing his argument against it mainly on what seemed to him the insuperable difficulties of management that would arise in this case. But such views *define* Evolutionary Socialism. They do not substantially differ from those which the leader of German Revisionism, E. Bernstein (see below, Part IV, ch. 5, sec. 8b), was to defend thirty years later. Naturally, they were gall and wormwood not only to Marxists but to all socialists who base their argument on the thesis of inevitably increasing misery and for whom the revolution is an essential article of faith. And Mill's teaching on the subject, precisely because it was so perfectly honest and because it expounded unpalatable truth in evident sympathy with the Ultimate End, grew much more distasteful to them than would have been straight hostility. All this is very important for understanding Mill's *Weltanschauung*—particularly for those of us who hold that a man's class interest or philosophy will determine his economic theory and his views on economic policy, and who have been taught to look upon the *Principles* as a verbalization of bourgeois ideology.

The success of J. S. Mill's *Principles* was sweeping and much more general, also much more evenly distributed over all countries in which economics received attention, than was that of Ricardo's. This was primarily due to a happy combination of scientific level and accessibility: Mill did present analysis that satisfied competent judges, yet, barring very few points that proved stumbling blocks, every economist could understand him. The book's many editions measure only its direct influence. To this must be added, so far as teaching is concerned, the litter of other textbooks it produced. Both students and general readers seem to have experienced a need for a still simpler presentation, even in England. And this demand was provided for by Fawcett.[6] On a higher level, even people who accepted Mill's claim of finality in substance could not fail to discover that many individual stones in his structure were loose. The most eminent of the English economists *of this period* who undertook to mend the structure—with debatable success—was Cairnes.[7] He may be called Mill's pupil, for he always reasoned with reference to the latter's teaching—even where he did not mention the fact explicitly—and he entertained toward Mill, as his correspondence shows, feelings that can be rendered only by the term 'reverence.'[8] Nevertheless, he sometimes criticized Mill sharply and, by virtue of this criticism, constructed something that, though entirely within the Millian groundwork, was in some measure his own. He was a born, but not a very original, theorist. Though most of his contributions have been sterile, his work, both analytical and methodological, marks an important stage. In calling him a born theorist, we must not forget however—as has been forgotten by some critics, particularly of the German historical school—that the bulk of his working hours went into practical problems and that it was his 'factual' contribution (in particular his *Slave Power*, 1862), which accounts for his reputation with the English public of his time.

---

[6] Henry Fawcett's (1833-84) *Manual of Political Economy* (1863) ran through six editions in his lifetime. The heroic energy of this eminent man, who lost his eyesight at twenty-five and nevertheless taught, wrote, practiced sports, was an active and independent Member of Parliament, and even a successful cabinet minister (Postmaster-General), cannot be sufficiently admired: he rightfully commanded the highest respect of his fellow economists. He was Marshall's predecessor in the Cambridge chair. In a history of economic analysis, however, he must rank below many far lesser men and no attempt can be made to do justice to him.

[7] John E. Cairnes's (1823-75) career—if career is indeed the word to be used—as a research worker, writer, academic teacher, and, though behind the scenes, politician was marred by ill health, the obvious reason why he failed to fill to the full the measure of his great ability. Even so he attained front rank: everyone would have mentioned him when asked, after Mill's death in 1873 (Jevons not being as yet appreciated according to merit), who was England's first scientific economist. The work of his that is for us the most important, *Some Leading Principles of Political Economy Newly Expounded*, appeared in 1874. Nevertheless, we allocate its author (unlike Jevons, whose *Theory* was published earlier, i.e. 1871) to the period under survey, because he expounded the old analytic economics and explicitly distanced himself from the new, which had just emerged into the light of day—showing, in doing so, that he entirely failed to appreciate its significance and possibilities. We range him, therefore, with the 'classics' (in quotes) but not with the Ricardian school. He belongs in Mill's group and there is the same reason as in the case of Mill for not calling him Ricardian. Of course, we might have deferred notice of him until the next period and made him, with Sidgwick, Nicholson, and others, a member of the group of 'survivals.' The other work of his that matters to us is his *Character and Logical Method of Political Economy* (1857), a landmark in the history of methodology.

2. Scope and Method: What Economists Thought They Were Doing

The preceding chapter has given us some idea of what the economists of that period actually did. We shall see presently how far their work reflected itself in J. S. Mill's *Principles*. But it is one of the characteristic features of the period that economists began to interpret themselves, that is to say, to theorize on (or to 'rationalize') their own aims and procedures. In research as elsewhere we first act and then think. It is only when a field has grown into an established science that its votaries will develop an interest, not untinged with anxiety, in problems of scope and method and in logical fundaments generally. This is perfectly natural, although excessive activity of this type may be a pathological symptom—there is such a thing as methodological hypochondria. The emergence of that interest—almost, though not quite, absent before—is indicative of the relative maturity that economics then gained. The results that this interest produced are, in themselves, of no great importance for us. We are all of us bad interpreters of ourselves and untrustworthy witnesses to the meaning of our practice. But precisely because of this, we cannot afford to neglect the period's methodology entirely. For critics have taken it literally, and hence it has become a source of misunderstandings concerning the scope and meaning of 'classic' economics.

(a) *Definitions of the Science.* We know that economists had experienced a need for defining their field even before A. Smith. During the period under discussion, their sense of responsibility for a distinct field having grown much stronger, practically all the writers of treatises tried their hands at defining it. Here are a few samples. J. B. Say defined Political Economy, by way of subtitle, as *exposition de la manière dont se forment, se distribuent et se consomment les richesses*. McCulloch defined Political Economy as the 'science of the laws which regulate the production, accumulation, distribution, and consumption of those articles or products that are necessary, useful, or agreeable to man and which at the same time possess exchangeable value' or the 'Science of Values' (*sic!*). According to Storch, Political Economy is the science 'of the natural laws which determine the prosperity of nations.' Senior's Political Economy is 'the Science which treats of the Nature, the Production, and the Distribution of Wealth.' J. S. Mill contented himself in the *Principles* with 'the nature of Wealth, and the laws of its production and distribution, including: directly or remotely, the operation of all the causes by which the condition of mankind . . . is made prosperous or the reverse.' Roscher said: 'Our aim is simply to describe man's economic nature and economic wants, to investigate the laws and the character of the institutions which refer to the satisfaction of these wants, and the greater or smaller measure of success they have had.' These examples will suffice to give an idea. If we realize that it is hopeless and, moreover, pointless to try to frame a definition that will fit all the activities of the economics profession, we shall not feel inclined to judge harshly any of the obvious inadequacies of these and other definitions. Certain features are worth noting, however.

---

[8] A few of Mill's letters to Cairnes have been published by Mr. Hugh S. R. Elliot (ed. *Letters of John Stuart Mill*, 2 vols., 1910). The correspondence I mean, however, has been published by G. O'Brien in 'J. S. Mill and J. E. Cairnes,' *Economica*, November 1943. It whets one's appetite for more.

All the definitions of the period emphasize the autonomy of economics as against the other social or moral sciences—which is, of course, perfectly compatible with the recognition of close relations. Most of them emphasize its analytic (scientific) character.[1] Both these facts, though they may not be to the taste of every critic, should be registered as landmarks on the road of analytic economics. A third fact must also be noted, however, because it gave rise to one of the most important, as well as irritating, of those misunderstandings to which I alluded above. The reader will observe that the definitions quoted are none too specific as regards the facts and problems that are to come within the scope of economics: J. S. Mill's, for example, reads like a comprehensive catchall, and even Senior's, taken by itself, leaves the reader in doubt as to what it is that Production and Distribution of Wealth imply, since the whole of a society's institutional pattern is obviously relevant to production and distribution. Now, the 'science' to be defined was, of course, called Political Economy.[2] Most continental writers used this term in a very wide sense. But most of the leading Englishmen, and especially James Mill and Senior, confined it to what is perhaps more properly called economic theory, and it is to this that their methodological pronouncements referred.[3] To critics, this looked like a tremendous difference in attitude and outlook. They felt that the English 'classics' had no eye for anything but 'wealth,' that their political economy was nothing but speculative 'chrematistics' (Sismondi) and so on. But we have already seen that this was not so. Their practice proves that they did not mean to restrict either their activities or their interests. What they did restrict was the use of a word. Thus, Senior would indeed have excluded from his political economy any factual analysis and any treatment of welfare problems. But what did that matter if at the same time he welcomed both to what he called the Great Science of Legislation?[4]

---

[1] This seems to indicate a break with the past, if we go, e.g., by Sir James Steuart's definition or by the one A. Smith offered at the beginning of the Fourth Book of the *Wealth*. But the break is more apparent than real. On the one hand, some authors, Sismondi for instance, kept to the old practice of defining economics by a practical aim. On the other hand, most of A. Smith's work is genuinely analytic in nature in spite of that definition; and the economists of the period continued to proffer value judgments and to recommend policies in spite of their definitions. This will be discussed below in subsec. c.

[2] With the exception of *Staatswirtschaft*, which was used by some German writers, the terms used on the Continent, even *Nationalökonomie*, were equivalents of Political Economy. The term Economics came into use in the subsequent period and then only in England and the United States. The German equivalent of this, *Sozialökonomie* or *Sozialökonomik*, never caught on.

(b) *Methodology*. From the standpoint thus gained we have no difficulty in absolving, once more, the 'classics' of any major errors of procedure. Their procedures were crude and often clumsy. Many of their controversies arose from nothing but an inability to see the opponent's point and some were purely verbal (as are many of ours).[5] The ridiculous 'method' of trying to analyze a ***phenomenon*** by hunting for the meaning of a *word* was rampant. But such as they were, the procedures actually used were not open to any serious objection of principle. They were thoroughly sensible and exactly what the nature of each type of problem would suggest to minds that were armed with little more than simple common sense. The 'classics' theorized in order to straighten out points that involved some logical complications; they assembled facts whenever they thought it useful to do so. The same cannot, however, be said about their methodological pronouncements, even apart from the fact that these—at least the English ones[6]—referred to economic theory alone.

---

[3] Realizing the danger that lurked in this terminology, Archbishop Whately made the unsuccessful suggestion: to replace the term Political Economy *in this sense* by the term Catallactics—from καταλλάττειν, to exchange. In this he showed his usual good sense. But having failed to make his meaning clear, he himself was misunderstood and thus really made matters worse. The reader will not have to tax his imagination very heavily in order to visualize how this must have struck critics: What!—Political Economy, the science of the economic fate of humanity, entirely reduced to a miserable theory of bargaining!

[4] J. S. Mill adopted instead the term Social Philosophy.

[5] One of the points at issue between Ricardo and Malthus was, e.g., whether the rent of land owed its existence to the 'bounty' or to the 'niggardliness' of nature. Nothing shows so clearly the primitivity of the analytic apparatus of the time as does the fact that two able men could actually discuss whether the return to a factor is due to its productivity *or* its scarcity!

[6] The most important methodological treatises of the period are: Senior's *Four Introductory Lectures on Political Economy* (1852); Cairnes's *Logical Method*; and J. S. Mill's fifth essay in *Some Unsettled Questions* (this essay was first published in the *Westminster Review*, 1836) and the relevant passages in his *Logic*. Several critics have held that Mill's position in the latter differed from that he had taken in the essay. This is a misunderstanding. The essay deals with the methodological aspects of 'political

But in most cases it is possible to put matters right by means of small corrections. Thus, most economists, J. B. Say and J. S. Mill in particular, thought altogether too much of the analogy with the physical sciences, which the latter declared to be the 'proper models' for economic theory (*Autobiography*, p. 165)—a point for critics to fasten on but actually irrelevant, since no practical use was made of it.[7] J. B. Say, while correctly emphasizing that economics is an observational science, nevertheless called it 'experimental.' But this can be easily corrected into 'empirical.' Furthermore, practically all economists used the term Law or even Natural Law, the avoidance of which would have saved them much obloquy from philosophy-minded critics. But this habit was quite harmless, since what they really meant was nothing but Montesquieu's 'necessary relations' between economic phenomena or Marshall's 'statements of tendencies.' In view of J. S. Mill's insistence on 'the very limited and temporary value of the old political economy,' there is no excuse for later critics who harped on those words. In fact, all the really valid points in the latter's methodological credo could have been copied out from Mill. Again, Mill used the term *a priori* in a misleading sense [8] and also placed unnecessary emphasis upon 'deduction.' This was perhaps responsible for the absurd argument of later times about 'induction vs. deduction,' but, always remembering that he thought of the theoretical apparatus of economics when speaking of methods of political economy, we readily see that it never caused any errors in practice.[9] Finally, as regards the method of 'isolating' economic phenomena or motives, or of abstracting from noneconomic ones, not only the practice of the 'classics' but even their methodological rationalization of it was free from serious error. It is difficult to believe that any critic who raises objections on this score can

---

economy' in the sense of economic theory. The passages in the *Logic* deal with the methodology of a much wider sector of the social sciences, mainly with what is called economic sociology in this book. The epistemological situations of the two fields differ substantially, and there is no contradiction between prescribing 'deductive' methods for the one and 'inductive' (or 'inverse deductive') methods for the other. The chief reason for this is that economic theory, owing to its quantitative character, admits of systematic elaboration to a much greater extent than does the analytic apparatus of any other social science.

[7] We have already observed that the introduction of the terms Statics and Dynamics does not involve any such use, i.e. any borrowing of a method from any physical science. Nor do economists borrow from mechanics when they employ the term equilibrium any more than does a bookkeeper who 'balances' an account.

[8] This is all the more surprising, because in his *Logic* he even made geometry an empirical science and because, though not an empiricist to 100 per cent, he certainly was more of an empiricist than was Kant.

[9] This, to repeat, is the real test. The literal meaning of a methodological profession of faith is of little interest except for the philosopher. Alternatively, our test may be formulated by saying that any objectionable piece of methodology is immaterial whenever it can be dropped without forcing us to drop any result of the analysis that is associated with it.

have studied J. S. Mill.[10] Of course, this statement must be understood to refer to the principles of isolation and abstraction per se as the 'classics' applied them for *the purpose of carving out the domain of purely economic research.* Only, so far as this goes, I maintain that, in principle as well as in practice, their procedure did not differ either from that of A. Smith [11] or from that of later economists as formulated by the later methodologists, Carl Menger and John Neville Keynes (see below, Part IV, ch. 4), and as accepted, around 1900, by a large majority of non-German economists. But I do not maintain that individual 'classic' writers, when reasoning within that domain, always 'isolated' relevant factors and 'abstracted' from others faultlessly. This would be absurd on the face of it, because it would imply that practically all their propositions were faultless: any criticism that does not charge either logical error or misstatement of facts can be formulated as an objection to the manner in which the criticized author 'isolates' or 'abstracts.'

The distinction that I have just tried to convey will help us greatly in understanding the methodological situation of the period, that is to say, the nature and extent of differences about 'method' that then existed among economists. At first sight, we have the impression that the *scientific* controversies of the times turned largely upon method. Thus, the two most famous and most prolonged controversies, the one on value and the one on general gluts, speedily led to the familiar situation in which, no progress being made with more concrete arguments, the parties fall back upon objections to one another's methods. In itself, this means little beyond admission of inability to convince the other man, coupled with a declaration of being unconvinced by him—or, in a word, deadlock. For instance, when in the controversy on gluts, Malthus (and Sismondi) objected to Ricardo's procedure as too abstract and Ricardo himself emphasized the abstract nature of the argument,[12] they simply verbalized a sigh of despair. It would be quite wrong to infer that Malthus and Sismondi really objected to Ricardo's 'method' in the sense in which this word came to be used in the later Battle of Methods (see Part IV, ch. 4). That this was not the case can be established by analysis of their own modes of reasoning: these were 'theoretical' in the same sense as was Ricardo's—just as Lord Keynes's theory is theory in the same (logical) sense as is Marshall's. In other words, Malthus and Sismondi theorized in a different way and partly with an eye to different sets of facts, but their practice proves that they had no objection to theorizing per se, such as had, for a time, the later Schmoller school or the American institutionalists.

---

[10] As a matter of fact, men like Roscher, who had mastered J. S. Mill, did not raise any such objection. But then, as will be shown presently, he was really no critic of the 'classics' in the sense in which this implies a methodological creed, incompatible with theirs. The majority of later German critics, however—those of the genuine historical school—cannot have had much first-hand knowledge of Mill or of the 'classics' in general, for it is hard to believe that if they had they could have misunderstood Millian methodology as completely as they did: they argued rather against a wrong picture of it that had become fixed by the time they wrote. And, considering their absorption in a research program of their own, this is after all not so difficult to understand. But what about Ingram (see below, Part IV, ch. 4)? How was it possible for him to preach the gospel of a 'new economics' that took its methodology from Comte? The only answer I am able to offer—and which must suggest itself to any professional who makes a study of Ingram's *History of Political Economy*—is that both his knowledge of economics and his interest in it did not go beyond general 'philosophies' that were inspired by generous enthusiasm for the great slogans of his day but never came to grips with real problems. His other objections to 'classic' economics point to this conclusion still more clearly than does his Comtist objection to an autonomous economics.

[11] This is so important as to justify repetition: A. Smith's work *looks* less 'abstract' because it includes so much factual information that the *specialized* later works on economic theory did not include—but left for other specialized works to provide. But where he does move within the orbit of economic theory, his reasoning is not less abstract than is, say, Ricardo's. With the latter, 'abstractness' shows more because he confines himself to topics of an 'abstract' nature, and does not provide illustrative foliage, but this is all.

But was not *this* objection (against theory per se) raised by other people? It was, but only in isolated instances that had no significant influence upon the work of a large majority of economists.[13] One such root-and-branch objector was Comte. But as we have seen, he exerted no perceptible influence *within the period* and on *economists*: J. S. Mill, so far as technical economics is concerned, yielded not an inch. Another was Le Play. He initiated an important program of research but, for the rest, he was hardly known among the economists of the period. I doubt whether R. Jones and B. Hildebrand can be called root-and-branch objectors. But even if they can, they were no more than forerunners. Cliffe Leslie did not declare for a distinctive historical method in economics until 1876. Ingram did not raise the flag of his New Economics until 1878. Knies,[14] it cannot be too often repeated, was primarily an economic theorist and, for the rest, an able general economist without any

[12] For, though 'abstractness' is usually urged *against* an argument, it may also serve in its defense. Marxists, in particular, frequently—and in some cases with justice—save a perilous situation by yielding the doctrine (in controversy) on one level of abstraction with the reservation that the same doctrine is quite right on a higher level of abstraction.

[13] I am not speaking now of extra-scientific objectors such as Carlyle. Nor am I speaking of those objections that arise from the general public's dislike of anything that looks like a complicated argument, nor, finally, of those objections that simply express everyone's natural preference for his own chosen type of work.

[14] As already stated, Knies's chief work and also the better part of his activity as a teacher belong to the next period. But the only one of his writings that connects him with the historical school appeared during the period under survey: *Die politische Ökonomie vom Standpunkte der geschichtlichen Methode* (1853; greatly enlarged, 1883). This book presents an interesting problem. It expresses not only a sense of the general flux of social institutions and of the impossibility of framing universally valid 'policies'—and other things that the author could have just as well taken from J. S. Mill—but actually outlines essential parts of the Schmoller program. But the modes of procedure actually employed in all his subsequent publications are so many disavowals of these principles. As a teacher, too, Knies was very far from inculcating economic historicism.

distinctive bent as to method. As for Roscher, who described Ricardo and Malthus as 'political economists and discoverers of the first rank' and who went out of his way to express agreement with J. S. Mill's methodology,[15] a comparison of his *Grundlagen* with J. S. Mill's *Principles* fails to reveal any fundamental difference in procedure—he even speaks of natural laws. It is true, nevertheless, that he laid claim to having used a historical or 'physiological' method. But, as is evident from Chapter 3 of the Introduction to that work, all he meant by this was to dissociate himself from what he called the 'idealistic' method that prescribes norms for an ideal state of society, whereas he wished to describe things as they are 'after the manner of the investigator of nature' [16] (op. cit. vol. I, p. 111). We therefore emerge with the result that, barring isolated rumbles, the Battle of Methods had not been engaged as yet and that—taking the word method in the sense that is relevant here—methodological peace substantially prevailed. This was also Cairnes's opinion.

(c) *The Science and the Art.* Most of the writers of standing who paid serious attention to the fundamental questions of methodology clearly saw, and strongly emphasized, the distinction between arguments about what is and arguments about what ought to be: the distinction between the 'science' of economics and the 'art' of policy.[17] But it would be a great mistake to read into their statements the meaning which this distinction acquired later, when the question of 'value judgments' was raised. Senior, who was more explicit on the point than was anyone else, said indeed that the economist's conclusions 'do not authorize him in adding a single syllable of advice.' But by this he did not mean that the economist as a scientific worker is debarred from presenting practical advice because such advice presupposes ultimate valuations that are extra-scientific by nature—preferences that are beyond the range of scientific proof. This is the point of view that was taken by Cairnes (who did not, however, adhere to it in practice) and later on, more explicitly, by Sidgwick and by M. Weber. Senior and Mill and their contemporaries did not mean this at all. They merely meant that questions of economic policy always involve so many noneconomic elements that they should not be dealt with on the basis of purely economic considerations—which, by the way, in itself suffices to show how little there is in the common indictment that the

[15] W. Roscher, *Grundlagen* (English trans., *Principles of Political Economy*, 1878, vol. I, p. 106n.).

[16] This does not apply, without qualification, to L. Wolowski's 'Preliminary Essay' that Roscher's translator, J. J. Lalor, prefixed to the English translation (1878). In 1878 things looked different and, by a not unnatural confusion, Lalor spoke of Roscher as the 'founder' of what was *then* the Historical School. This gives a completely wrong picture.

[17] Confusions between the two and even denials of the validity of the distinction were of course frequent; but not more so than they have been at any later time, including the present. In the large majority of cases the distinction was firmly kept in view. For France, Charles Coquelin's article on political economy in the *Dictionnaire de l'économie politique* is typical in this as it is in other respects. Roscher's emphasis upon the distinction between what is and what ought to be deserves particular notice.

English 'classics' never saw anything but the economic aspects or, still worse, the wealth or even the profit aspects of things. But none of them really questioned the validity of value judgments that were based on 'philosophical' grounds and took proper account of the noneconomic as well as the economic elements of a given case—the value judgments of 'the writer or statesman who has considered all the causes which may promote or impede the general welfare' as distinguished from 'the theorist who has considered only one, though among the most important of those causes' (Senior, *Outline of Political Economy*, p. 3). This, as we have seen, was also J. S. Mill's opinion and in fact practically everyone's. There is, of course, sound sense in it: one could only wish that the economists of that (or any) period had never forgotten this piece of wisdom—had never been guilty of the Ricardian Vice.[18] However, it still remains true that the real problem of value judgments never occurred to them. *To the end of the period, economists considered their recommendations concerning policy as scientific results which followed from scientific, though not purely economic, analysis.* In this sense they were after all, as later critics sneeringly remarked, purveyors of recipes. Fortunately they also were more than that.

3. What Mill's Readers Actually Got

Mill's readers got, in the first place, factual information to the extent of about one-sixth of the book. On the face of it, this is a smaller proportion of space than either A. Smith or Roscher allotted to the presentation of facts, and what there is of this factual presentation is extremely ill-balanced, facts about 'peasant proprietors,' for example, taking a share more commensurate with Mill's own interest in the subject than with its probable interest for his readers. But this may be a wrong view to take. As Mill's preface emphasized, his treatise abounds in practical 'applications.' And these have reference to factual material that Mill often failed to present, perhaps because he assumed that his readers could easily supply the deficiency from universally accessible sources—such as the work of Babbage.[1] If we count as 'factual' all discussions in the book that in this sense presuppose factual information, although the information is not actually presented, then, if I have estimated with anything like accuracy, the 'factual' portion of the book increases to a little more than two-thirds of the whole, a little less than one-third being left for exposition of the analytic apparatus. In the second place, his readers got a fairly thorough—but none too thorough—grounding in 'theory.' However, as has been pointed out already, no contact whatever is made with any statistical *method*.

---

[18] See above, ch. 4, sec. 2.

[1] Charles Babbage, *On the Economy of Machinery and Manufactures* (1832). This work, which was widely used (also by Marx), is a remarkable performance of a remarkable man. Babbage (1792-1871), who was one of Newton's successors in the Lucasian chair of mathematics (Cambridge), one of the founders of the British Association for the Advancement of Science (1831) and of the Statistical Society, and a versatile writer on many subjects, was also an economist of note. His chief merit was that he combined a command of simple but sound economic theory with a thorough first-hand knowledge of industrial technology and of the business processes relevant thereto. This almost unique combination of acquirements enabled him to provide not only a large quantity of well known facts but also, unlike other writers who did the same thing, interpretations. He excelled, among other things, in conceptualization: his definitions of a machine and his conception of invention are deservedly famous. It is interesting to note that in some points he recognized the priority of Gioja, whose name should in

From another standpoint, we can illustrate Mill's range of topics by means of the following list of headings that, as the reader can easily satisfy himself, could be lengthened both by including further minor items and by dividing up some of the major ones: prices, price fixing, competition, custom, monopoly; wages and employment, wage policy, trade unions, poor laws, and other items of the *Sozialpolitik* of that age; socialism, with special attention to Saint-Simonism and Fourierism; producers' and consumers' co-operatives; future of the working class; education; population; enterprise and forms of enterprise, capital, profit, interest; saving and investment; technological advance; money and banking, central banking, foreign exchanges, government paper money; crises; foreign trade; colonies; private property, inheritance; partnerships, companies, bankruptcy legislation; rent, ownership of land, primogeniture, peasant proprietorship, metayage, cotter tenancy, slavery; 'progress,' 'maturity' (stationary state); government policy and government control; grounds for and limits of laissez-faire; public finance, especially taxation and public debts. I do not think that this list is conspicuous for either narrowness of range or remoteness from the practical issues of the day. It should be observed particularly that all that interested later generations could have been hung on hooks presented by Mill without upsetting his system. For instance, later institutionalists could have inserted into Mill's niches all the additional material of a specifically institutional nature that they might have wished to insert, *without thereby destroying the general character of the treatise*: there was room for everything within its spacious folds; and everything could have come to it as a development of existing points, nothing need have come to it as a revolution.

J. S. Mill arranged his material in five books: 'Production,' 'Distribution,' 'Exchange,' 'Influence of the Progress of Society on Production and Distribution,' and 'On the Influence of Government.' The last also contains things other than public finance but nevertheless mainly corresponds to A. Smith's Fifth Book. In Book IV, the shortest, Mill concentrated what he had to say on the subject of economic evolution—a happy innovation in exposition. The titles of the first three books suggest the influence of Say's arrangement or, rather, a not very felicitous attempt to improve upon it. The central theory of value, which should come first on logical grounds (and does come first with Ricardo and Marx), is presented in Book III as if it had to do only with the

---

fact be coupled with his. By way of contrast to his sound well-balanced treatment, I mention A. Ure's (*Philosophy of Manufacture*, 1835), who also presented interesting facts, but was not Babbage's equal as an analyst.

'circulation' of goods and as if production and distribution could be understood without it. This is worth mentioning because it points to a fundamental weakness of the 'classic' construction. I do not accuse the 'classics' of having failed to sense the pivotal importance of the analysis of value (choice) which is, if I may say so, the specifically economic element about the economic process. But there is some truth in Professor Knight's indictment that the 'classics' had 'no clear or definite conception of the meaning of *economy* as a process of maximizing a value return' and that 'the problem of *distribution* . . . was not approached as a problem of valuation at all.'[2] To this extent, we must qualify our recognition of Ricardo's chief merit. He and all the 'classics,' including Mill, did indeed make progress toward the acquisition of an analytic apparatus that would unify all purely economic problems; but, partly owing to the shortcomings of their groundwork, they never realized its possibilities to the full. They still divorced production from distribution—J. S. Mill even took credit for doing so—as if they were governed by different 'laws.' The first to point this out was Ferrara.[3] But Say's and Mill's combined authorities kept this plan of exposition alive for many decades to come. It is not worth our while to discuss its variants. Roscher, for example, has: Production, Circulation, Distribution, Consumption, Population—including Credit with Production.

The five books are preceded by 'Preliminary Remarks,' which, among less interesting things, contain a short sketch of what we should call the evolution of economic society—a universal economic history in a nutshell. This, of course, is not in itself surprising in a work that aimed at doing again what A. Smith had done. But much beyond what tradition leads us to expect from Mill is his handling of the factors to which he attributes causal roles in the shaping of the fortunes of a society or country. Environment, race (*racially* differentiated quality of human material), class structure, habits or propensities, combine to make a colorful and, what is more, a very realistic picture. There are no intellectualist and in particular no utilitarian errors about it: 'knowledge' is considered as a consequence as well as a cause 'of the state of the production and distribution of wealth,' and objective conditions receive more emphasis than ideas or principles. Such prefatory sketches of economic history—though of course not always of this quality—became more and more popular as the century wore on: Marshall's is the peak performance of this type.

---

[2] F. H. Knight, 'Ricardian Theory . . .' op. cit. p. 6. The second part of that statement goes perhaps too far. But Professor Knight supports it by a highly significant passage from a letter of Ricardo to McCulloch, where the former avers in so many words that the relative distributive shares 'are not essentially connected with the doctrine of value.' Though this cannot be taken literally—for it could be refuted from Ricardo's own argument—it does show that the full implications of the fact that capitalist distribution is a value phenomenon were not clearly seen even by Ricardo. They were seen by Marx.

[3] In his *Prefazione* to Say.

4. THE INSTITUTIONAL FRAME OF THE ECONOMIC PROCESS

(a) *The Institutions of Capitalist Society.* Economic sociology covers, first, the facts of economic behavior from which economists forge certain assumptions and, second, the institutions that characterize the economic organization of the societies to be studied. 'Classic' practice as regards the former will be more conveniently discussed in the next chapter. As regards the latter we must distinguish three questions. Many writers, primarily the English theorists—such as Ricardo, James Mill, and Senior—did not bother to specify the details of the institutional frame they visualized, but took them for granted. Is it true, as has been averred so often, that they believed in the permanence of the capitalist order of things or even that laissez-faire capitalism is the only possible form of civilized society? What were the institutions they took for granted? When they did discuss them, what methods did they use?

The first question must, I think, be answered in the negative. It is true that Ricardo, for example, by virtue of the very fact that he failed to specify his institutional assumptions, creates an impression to the effect that the problems of social change were beyond his range of vision. But this does not follow. All that follows from his practice is that they were beyond his chosen field of inquiry. There is no reason to believe that, had he offered a description of the institutional frame, this description would have differed significantly (though his value judgments might have) from that of J. S. Mill, who, aiming as he did at systematic completeness, was more explicit. But as we know already (see sec. 1, above) there cannot be any doubt whatever about the latter's awareness of the historical relativity of social institutions and also of some at least of his 'economic laws.' To this extent, the current belief that this awareness was confined to isolated forerunners of later historicism, such as R. Jones and Sismondi, is certainly erroneous. It would be nearer to the truth to say that explicit belief in the permanence or in the unsurpassable excellencies, for all times, of capitalism occurred only in isolated instances.

The reader should observe, however, that this does not amount to crediting the 'classic' theorists with the idea that the capitalist order is only a historical phase and bound to develop, by virtue of its own inherent logic, into something else. This idea belongs to Marx alone. Even J. S. Mill held only that men could, should, and would change capitalist institutions through a rational perception of what he considered to be their defects. He did not hold that institutions would change of themselves or even that they would have to be changed because they would become *objectively* untenable. He saw that 'opinions . . . are not a matter of chance'[1] but the product of social conditions, and we might feel tempted to develop this in the Marxist direction. But this would hardly be justified: we must, I think, leave him in the citadel of eighteenth-century faith in intellectual progress, from which he occasionally sallied forth, no doubt, but to which he always returned. Practically, this matters but little. Scientifically, it makes a great deal of difference.

---

[1] Last but one paragraph of Book II, ch. 1, § 1.

The second question is an easy one. Economists, wishing to serve their time and countries, took for granted—and reasoned in terms of—the institutions of their time and countries. Since conditions differed as between different countries, this accounts for certain differences in outlook that, at the time and later, were erroneously construed as differences of analytic principle. The traits of the picture that were selected by the English 'classics' stand out very clearly. They envisaged the legal institutions (if we disregard the historical survivals that suggest another type of society) of a private-property economy that left so much room for free contracting as almost to justify the practice of economists to leave limitations out of consideration. This only means, of course, that no account was taken of limitations explicitly and consciously. As a matter of fact, English economists always reasoned with reference to the actual extent of the sphere that English law and administrative practice left for private decision and to the actual use that was being made of this freedom within that sphere—subject to the prevailing moral habits. Failure to be specific about all this exposed the English 'classics' to much mistaken criticism concerning their apparent neglect of ethical aspects.

The unit of that private-property economy was the firm of medium size. Its typical legal form was the private partnership. Barring the 'sleeping' partner, it was typically managed by the owner or owners, a fact that it is important to keep in mind in any effort to understand 'classic' economics. The facts and problems of large-scale production and, in connection with them, those of joint stock companies were recognized by economists after everybody else had recognized them. They received textbook status at the hands of J. S. Mill, who duly blamed A. Smith for his narrow views on corporate business—forgetting only the detail that there was little merit in realizing its importance in 1848 and that actually he was doing no more than what A. Smith had done, namely, describing with sober and somewhat platitudinous common sense that which stood before his eyes. Two further points deserve notice.

In the normal case, these firms were supposed to work under what the 'classics' called Free Competition. With them, this competition was an institutional assumption rather than the result of certain market conditions. And so firmly were they convinced that the competitive case was the obvious thing, familiar to all, that they did not bother to analyze its logical content. In fact, the concept was usually not even defined.[2] It just meant the absence of monopoly—which was considered as abnormal and was vigorously condemned,[3] but was not properly defined either—and of public price fixing. J. S. Mill took credit, not without justification, for two important steps. First, he emphasized the importance of customary prices, mainly for earlier civilizations and for the Continent, but in certain cases, such as rent and professional fees, also for England. And, second, he emphasized the fact, though custom was the only reason he gave for its existence, that competition often 'falls short of the maximum' and that in this case a general correction must be applied, 'whether expressly mentioned or not,' to all conclusions arrived at on the hypothesis of perfect competition (Book II, ch. 4, § 3). Into such a picture co-operative price setting could enter only, if at all, as another deviation from normal practice like straight monopoly and as a conspiracy against public welfare exactly as it does now. There was, however, an exception to this: in J. S. Mill's scheme of things, trade unions were a normal element of the institutional pattern and laws against them 'exhibit the infernal spirit of the slave master' (Book V, ch. 10, § 5).

---

[2] It is interesting to note that J. S. Mill in Book II, ch. 4, of his *Principles*, which deals with 'Competition and Custom,' while expressing a conviction to the effect 'that only through the principle of competition has political economy any pretension to the character of a science'—which presumably means that there is more of determinateness about prices and quantities of commodities in the case of competition than there is in other cases—he does not think it necessary to state what competition is. The only author to handle perfect or pure competition correctly was Cournot, who also indicated, though he did not formulate in so many words, a correct definition (see below, Part IV, ch. 7, sec. 4).

The other point to remember is this. Many English economists were severely critical of the English land system.[4] But when not engaged in criticizing it or in discussing alternatives, they also took it for granted in the sense that they reasoned with reference to it and to the English type of landlords who owned but did not operate large estates. In this particular case, however, reasoning in terms of existing institutions carried an advantage that may be made to stand out by contrast with the reasoning in terms of the owner-managed firm: landlords and farmers being different persons, it was easy for the theorist to keep their economic 'functions' distinct; owners of firms—'capitalists'—being then mostly the same people who also operated these firms, it proved less easy for the theorist to recognize this distinction of 'functions.' This teaches us an interesting lesson: it *may* happen, though we have no right to see in this occurrence more than a stroke of luck, that a *particular* historical pattern, which taken as a whole has nothing permanent about it, reveals facts and relations that are of general analytic importance. Usually, of course, it is the other way round, and we must always look out, on the one hand, for limitations that their particular institutional assumptions may impose upon the results of the 'classics' and, on the other hand, for possible justifications of these same results that may be found occasionally in the peculiarities of the social pattern they envisaged.

---

[3] For Roscher's unconditional eulogy of competition and his uncritical condemnation of monopoly, see op. cit., Book II, ch. 1, § 97.

[4] So much so as to be unable to see at all its strong points. I am not referring now to the political society and the cultural values it produced: a bourgeois radical cannot in fairness be expected to see these. But many economists also had no eye for the advantages of a system that separated the *administration* of land from the *operation* of it and thus e.g. eliminated the most serious of the problems of agricultural credit. Rational socialism could do worse than copy the system, replacing, of course, the landlords by a public agency.

Our third question—concerning the method used by the 'classics' in discussing social institutions—will be addressed, for brevity's sake, to J. S. Mill alone.[5] As an example, consider his views on inheritance.[6] The discussion culminates in the recommendations (a) that freedom of bequest be the general rule, except for a modest compulsory provision for descendants and for a provision to the effect that no person should 'be permitted to acquire by inheritance more than the amount of a moderate independence'; and (b) that 'in the case of intestacy, the whole property escheat to the State,' also with a proviso in favor of 'just and reasonable' provision for descendants. In themselves these recommendations and also the particular ideas of 'justice' that enter into them are only interesting from standpoints other than ours: to the historian of civilization they reveal part of the schema of cultural values that was harbored by a leading intellectual who belonged to the middle class and lived in the mid-Victorian era.[7] But there is, besides much pure ideology, also something behind those recommendations that is analytic in nature and admits of the application of a scientific method. Only, this scientific method is not the one we might expect. Mill's problem is not to explain, historically and sociologically, the origin and the various forms of the institution of inheritance. This, as he said in so many words in the case of the institution of property (§ 2 of Book II, ch. 1), is no concern of 'social philosophy.' What does concern the latter is the problem of social expediency, though not the expediency of any institution as it actually is, but as a community that is unhampered by any tradition or 'prejudice' might introduce it—under advice, I suppose, of the social philosopher. This is perhaps not the most scientific way of putting the matter but it indicates Mill's method of analyzing social institutions clearly enough: expediency of an institution turns upon its effect on, or role in, the economic organism—in practice upon the effects to be expected from given changes of a given pattern—and these effects Mill then proceeded to analyze. In doing so this fighter against prejudice proves himself indeed the most defenseless victim of prejudice against anything that is very far removed from his own mode of life or thought—displaying in this a deplorable narrowness of outlook[8]—but in themselves both the task and the method are scientific (analytic) in nature.

---

[5] This carries the disadvantage that our answer will be lopsided. Let me therefore state explicitly that more history-minded economists and, *a fortiori*, contemporaneous students who specialized in the history of institutions are not as a rule oblivious to the indictment I am going to level at Mill. His case is, however, important for general economics because he set a textbook fashion that prevailed far beyond the period under survey. The discussion of property and inheritance, e.g., that we find in the deservedly successful textbook of von Philippovich is exactly on Millian lines as far as its methodology is concerned.

[6] *Principles*, Book II, ch. 2 and Book V, ch. 9. This treatment of the same subject in two different parts of the treatise, which is highly inconvenient for the reader and a bar to any well-rounded exposition, is one of the many symptoms of the haste with which the work was produced.

[7] From Mill's essay on *Utilitarianism* it is clear that he was not blind to the doubtful standing of the concept of 'justice.' Yet he was no more able to do without it than were (or are) other economists. Even Ricardo occasionally finds some things 'just' and others 'unjust.' In Mill's case we cannot help discovering—perhaps with a wry smile—a marked association between what he thought right and proper and the modest privileges that he enjoyed himself. Socrates—an intellectual—should really have a moderately larger allowance than should a fool, he argued (as had his father), and if anything is certain, it is that J. S. Mill did not identify himself with the latter. The emphasis above upon 'moderate independence' points in the same direction. For only to the middle-class bourgeois is the desirability of anyone's 'moderate independence' as evident as it was to him.

(b) *The State in 'Classic' Economics.* In Chapter 2 of this Part we learned a number of facts about the 'politics' of the period's economists and about the meaning and limitations of what has been called the System of Natural Liberty. In Chapter 3, we made the acquaintance of several types of political sociology, among them the Marxist Theory of the State. In Chapter 4, we had the opportunity to notice, here and there, the positions taken by individual economists with respect to the role of the state in economic affairs. In this section, we shall disregard all this, and all philosophies, ideologies, and political preferences—which were in part simply the philosophies, ideologies, and preferences of the business class that, standing on its own feet economically, did not want anything from the state except legal protection and low taxes—including the political recommendations associated with them. Instead we shall concentrate on one question only: how did all this affect economic analysis? Or, since all this enters or influences economic analysis by way of the *assumptions* economists make about the nature of the state (governments, parliaments, bureaucracies) and its normal functions and efficiency: how far were the assumptions made by economists realistic, considering the historical conditions to which their analytic propositions were to apply?

My answer is that these assumptions reproduced tolerably well the actualities of the time in those economists' *countries*. Practically all economists *believed*—no matter what they *desired*—that, as J. S. Mill put it, laissez-faire was the general rule for the administration of a nation's economic affairs and that what was significantly called state 'interference' was the exception. And, though for different reasons in different countries, this was so in actual practice not only as a matter of fact but also as a matter of practical necessity: no responsible administrator could have held then, and no responsible historian should hold now, that, social and economic conditions and the organs of public administration being what they were, any ambitious ventures in regulation and control could have issued in anything but failure. For the rest, wide differences existed between the economists of different countries with regard to what public administration could and 'should' do. But, as has been pointed out in Chapter 2, they are largely accounted for by differences, not in economic principles, but in the actual conditions of different countries.[9] And practically all of them—so far as professional economists are concerned—come within the range covered by the phrase, 'differences of opinion as to the extent of the exceptions—necessary or only desirable, approved or disapproved—to the laissez-faire rule.'

---

[8] If the reader refer to Mill's text, he will presumably not agree with me. But this is only because he shares Mill's prejudices. However, our own prejudices are still prejudices.

[9] Of course this was not all of it, and one of the reasons why it was not is that different historical developments had, in different countries, induced different political doc-

The special case of England will illustrate this.[10] There, no revolution had occurred to sweep away the top-heavy structure of eighteenth-century bureaucracy, which was inefficient, wasteful, littered with sinecures, associated with unpopular mercantilist policy and even with political corruption. Before a new and more efficient structure could be erected, the old one had in any case—I mean, irrespective of what, if anything, one wished to put in its place—to be pulled down bit by bit in order to clear the ground. And until this had been done, the existing machinery of public administration was simply not up to any of those complicated tasks that modern regulation or *Sozialpolitik* involves. It is to the credit of J. S. Mill's judgment that he was aware of this. He was not on principle averse to a large amount of government activity. He had no illusions about any philosophically determined 'necessary minimum' of state functions. But he realized the superiority, which was in the circumstances simply not open to doubt, of the businessman's administration of the productive resources over what could possibly have been expected from the public official of his day. He realized more than that. No careful reader of his treatise can fail to notice the number of times he, after arriving at the result that something or other (for example, restriction of the income tax to consumers' expenditure) is 'desirable,' refuses to turn this value judgment into a recommendation because of insuperable administrative difficulties: they actually were insuperable *then*. It is true that the other English 'classics'—not to mention the anti-*étatiste* monomaniacs, whom that social situation produced, especially in France—not only failed to see that those conditions were essentially transitional but also advocated, as a matter of course, that the red tape that was being eliminated should never be replaced by anything: that government and bureaucracy should 'naturally' be confined to a certain minimum of functions. But even this, representing as it did a real tendency, does not *so far as it was an assumption about part of the institutional frame of the economic process* impair the value of their economic analysis.

But we can go a step further. From our argument it might seem to follow that, if 'classic' analysis, in the respect under discussion, was valid because its assumptions about the role of the state were realistic though time-bound, it must be invalid for any other period because those assumptions were time-bound though realistic. This is in fact true for a large number of propositions

---

trines about state and bureaucracy that led economists to 'absolutize' their nationally conditioned opinions, i.e. to exalt them into eternal truths. The situation was complicated by migration of ideas, such as the migration of 'Smithianism' to Germany, where it conquered not only many economists but also most leading bureaucrats. We cannot stay to analyze the consequences.

[10] It will be seen that what I am going to say applies to no other country. But it is not possible, in the available space, to do more than indicate the point of view from which such problems should be seen.

in applied economics—still more so for recommendations. But it is not so for the 'classic' analysis itself. We always need to understand whatever it is we wish to regulate or control. This means that, however comprehensive the economic tasks of government may be at any time, we always need theory of the 'classic' type as long as it is a question of regulation and control only—in socialism we need of course a different type of theory. We do not go to 'classic' economics for information about, say, the factors that account for unemployment because of its *analytic* defects. But the fact that its assumptions about the role of legislation and public administration do not fit the conditions of our time does not in itself constitute a valid reason for our refusing to do so. Of course, the reader will understand how difficult it must have been to accept this for later historians of economic thought, who were interested in little else but ideas, social doctrines or philosophies, and political recommendations, and who were in no position to decide which 'classic' propositions must, and which need not, be dropped when we drop any given element of their institutional frame.

(c) *The Nation and the Classes.* In concluding this section, I wish to advert to two of the many lacunae in our survey of the institutional aspects of 'classic' economics: we have not dealt with the manner in which the economists of that period handled the social phenomenon that we call Nation or Country; and we have not dealt with their conception of the class structure of society. The former is relevant for economic analysis in three ways. First of all, it is a factor—some would say the dominant factor—in the general sociology or social philosophy of many economists: of this all that needs to be said for the purposes of this book, has been said in Chapter 3 (especially under the heading Romanticism). From this we distinguish, second, the national viewpoint in economic policy, about which we have learned something in Chapter 4 (Carey, List), but which will be touched upon again in the section below that deals with foreign trade (ch. 6, sec. 3). Third, it is a question of considerable interest to ask how far the economists of that period took account of national differences of economic behavior and of consciousness of nationality as a motive of economic behavior: this question will be treated below (ch. 6, sec. 1). The subject of Social Classes offers a convenient transition from this to the next section.

In economics, as in all the social sciences, the term Class denotes two different things that, in strict logic, have nothing to do with one another. When we speak of Social Classes or of the Class Structure of Society, we mean to denote a real phenomenon that exists independently of the activity of research workers: actually or metaphorically, we may hold that a social class is an entity that thinks and feels and acts. But we also speak of classes when we mean nothing but categories that owe their existence to the classifying activity of research workers. Thus, when we speak of working-class movements, we are indeed referring to masses of individuals but of individuals that rally around a group standard and form, as it were, a psychological corporation, a social class. When we consider the group of all the people who derive their incomes from selling services (personal efforts), we find that we are combining social types that have very little in common and hardly ever feel and act in unison—such as street sweepers and movie stars, manual workers and executives, charwomen and generals: in short, we are considering a category that we have formed ourselves. If this were all, we should have merely to advert to the existence of another source of confusion in economic discussion and to make sure in each individual case what it is we mean or a given writer means when using the term Class—social classes that are red-blooded realities, or categories of participants in the economic process that are pale abstractions.[11] But associated with this simple distinction is an important issue that may as well be noticed at once.

Marx's two 'classes of participants in the economic process,' [12] capitalists and proletarians, are not mere categories but social classes. This feature is essential to the Marxist system. It unifies his sociology and his economics by making the same class concept fundamental for both. On the one hand, the social classes of sociology are *ipso facto* the categories of economic theory; on the other hand, the categories of economic theory are *ipso facto* the social classes. The importance of this feature becomes particularly clear when we observe its bearing upon class antagonism, which in this system is at the same time an exclusively economic phenomenon *and* the all important fact about all pre-socialist human history. We shall understand that from this standpoint any attempt to form economic categories other than social classes is bound to appear as an attempt to leave out or obscure the very essence of the capitalist process or, to use a phrase current among Marxists, to 'rob economic theory of its social content.' Such an attempt is not only tainted with 'apologetics': it is futile and cannot produce solutions of the real problems of economics.

But non-Marxist economics was not less bound to take, with increasing emphasis, the opposite view, and to look upon the very feature Marxists took (and take) pride in, as a blemish due to the survival of prescientific patterns of thought. This was the inevitable consequence of analytic advance that made more and more for a clear distinction of the purely economic relations from others with which they are associated in reality. In analyzing economic phenomena, categories other than those suggested by the class structure of society have proved more useful, as well as more satisfactory, logically. This does not involve overlooking any relevant class-struggle aspects, or simply class aspects, of the relations investigated.[13] All it does involve is greater freedom for all the various aspects of reality to assert their rights.

---

[11] Some modern economists call these abstractions Functional Classes. We ourselves shall, for greater clearness, use the term Categories, however objectionable it may be in some respects.

[12] Unfortunately, there is no good English equivalent for the German *Wirtschaftssubjekt.*

[13] The proof of this pudding is, of course, in the eating. No general professions of faith or general arguments about the impossibility of analyzing, e.g., distribution of income in terms other than the terms of social classes can settle the matter. Of course, the question is complicated by another, viz., the question of the validity of the Marxist theory of classes. But, in this connection, this is a side issue. Even if it were valid, the

As we shall presently see, the economists of the period under survey did take a great stride toward an economic analysis in terms of categories of economic types and away from economic analysis in terms of social classes. But they did not proceed in the logical way: that is, they did not work out a theory of social classes, insert it into their economic sociology, and then construct economic categories for use in economic analysis: this procedure would have required an awareness of the problems involved from which they were far removed. Instead, they took a short cut: they simply turned, with little modification, the social groupings that are known to the popular mind into categories of economic analysis. With the exception of Marx, whose analysis of social classes, however defective, is still analysis, they made no analytic effort. And the need for such an effort never occurred to them because, as a matter of fact, the social groupings of the man in the street were sufficiently drenched with economic meanings to make them adequate for the rough purposes of 'classic' economic analysis. The man in the street always had been greatly impressed by the landed aristocracy that towered over the rest of society. Hardly less distinctive and impossible to overlook was the position, on the other end of the scale, of the agricultural and industrial 'poor.' For the rest, the man in the street saw farmers, artisans, manufacturers, moneyed men, bankers, merchants and so on, rather than a single business class, and he would certainly have reserved other special positions for the professions. In the latter respect, 'classic' economists agreed with him more or less.[14] But for the rest of those groups, they (the 'classic' economists) did perform the modest service to analysis that consists in throwing them together, for some though not all purposes, into a single economic category, for which the label 'capitalists' soon came to be generally used in economic literature.[15]

Thus Marx, alone of all leading analysts, retained the class connotation of the categories of economic types, consciously and as a matter of principle. The prevailing tendency to get away from it, which he did

---

methodological necessity of a conceptualization adapted to the special tasks of economic analysis would still remain. Most modern socialists, by using modern theory, testify to their agreement with the view taken in this book. Much more important is it that Marx himself, in his analytic practice, agrees with us. For he uses his classes only for the purpose of interpreting the results that the capitalist economy produces; as will be seen presently, he does not introduce his classes as *actors* in his basic analytic work. He emphasizes indeed the social-class aspect whenever he can. But, except in the political sphere, his classes do not struggle with each other *as classes.*

[14] The analytic difficulty which the 'classic' wage analysis opposed to the inclusion of the professions in the labor category was in part avoided by those authors who described the professions as unproductive and thus excluded them from the economic society to which their propositions primarily applied. Those who counted skills as capital could also include them with capitalists.

[15] The public did not adopt it to any great extent until after 1900. But while the term Capitalist gained citizenship in the economist's lingo, the term Capitalism was, throughout the nineteenth century, hardly used except by Marxists and writers directly influenced by Marxism. There is no article under this heading in *Palgrave's Dictionary.*

not fail to notice, he simply put down as one of the symptoms of the degeneration of bourgeois economics that, so he held, had no longer the courage and honesty to face the real issues. By the same token, he noticed with approval those vestiges of the popular confusion of the two aspects that may be found in the earlier 'classics,' especially in Ricardo. The existence of such vestiges is what we should expect in a process of analytic development that was not only slow but also subconscious. But how important were they? It is true that Ricardo spoke of distribution of the 'produce of the earth' as a process of distribution between 'three classes of the community' (Preface). This does seem to imply class connotation. If, however, we wish to take this phrase literally, we must take the whole sentence literally—and this would make a physiocrat of Ricardo. Further, it is true that his theory of wages, so far as it fits any part of reality at all, fits only the wages of manual labor—of the proletarian *class*. And finally Ricardo, according to traditional interpretation, emphasized antagonism of class interests—the interests of the landlords, in particular, being held to be 'always opposed' to those of the rest of society. This, of course, is what Marx liked best and what other economists who also took it for an essential feature of Ricardo's economics, such as Carey and Bastiat, liked least. But as regards the old wage theory that Ricardo adopted, it is very obvious that he did not impart to it any class-struggle twist. And it seems much more realistic to see in its very partial validity the inevitable result of a defective analytic apparatus than of any intention to emphasize class aspects. As regards his general handling of class interests, two things must be carefully distinguished. Like most 'classics' Ricardo was much alive to political implications. Being one of the champions of free trade in corn, he thought of it as a political measure that was to be carried against the *economic* interest of a *social* class—which in this case would understandably merge in his mind. And this happened, of course, every time there was a political issue on the anvil. But this is all right—the political viewpoint brings in party strife and party brings the social-class element: nothing is further from my thought than any wish to argue for a treatment of *political* questions that neglects this class element and reasons in terms of an imaginary common good. But quite another question is the significance of the opposition of class interests in Ricardo's economic analysis per se. This reduces to propositions about the long-run tendencies of relative distributive shares (see below, ch. 6, sec. 6). He held, for example, that the landlord's share tends to increase at the expense, primarily, of the capitalist's share. This, however, does not constitute class antagonism either in the Marxist or in the usual sense. Marx, recognizing two classes only, saw class 'struggle,' economic *and* political, only between these two and thereby testified to his belief that opposition of interests *in the Ricardian sense* does not constitute class antagonism. In the usual sense, class antagonism means antagonism between social classes—a reality that manifests itself, for example, in the political arena. For this phenomenon to arise, the Ricardian antagonistic tendency in distributive shares is neither a necessary nor a sufficient condition. This seems to establish our thesis, namely, that the class connotations of Ricardo's categories are in fact no more than survivals and nonessential to his system; and that, in particular, Carey and Bastiat and all the writers who took similar lines were in error when, believing that the Ricardian tendencies in distributive shares spelled social warfare, they set about disproving them.

5. The 'Classic' Schema of the Economic Process

Into the sociological frame just sketched, the 'classics' fitted a schema of the economic process, the general features of which it is our next task to describe. In itself this task is simple enough. But it is rendered more difficult by the facts that the form the schema took in the classic (in our sense) work of the period, J. S. Mill's *Principles*, is of course not more than 'representative' of a large number of schemata that more or less differed from it; that even so it was the outcome of long discussions that were in part pointless, sometimes merely verbal, but which loom large to the backward glance; and that the state of analytic work looked very different at different stages. The very proposition that there was anything like progress toward clarification of the issues and improvement of the results of analysis will be voted a misrepresentation by readers who either forget, or on principle disapprove of, the aim and viewpoint of a history of *analysis*.

(a) *The Actors*. Any schema of the economic process must first of all settle the question of the *dramatis personae* to be admitted to the scene and thereby prejudge many of its features. These actors were, of course, firms and households and not social classes, or else there could not have been competition: this also applies to Marx's *theory*. As we know, these actors were classified by means of turning the social groups known to common experience into the three categories of economic types (or 'functional' classes): landowners, laborers, and capitalists.[1] Of course, this merely continued an old practice that had been sanctioned by A. Smith. Since the three were mere categories, each defined by an economic trait, it was recognized without difficulty that an individual was capable of belonging to two (for example, if he was an artisan) or to all three of them (for example, if he was a peasant, tilling his own soil). Marx, as we also know, substituted his two-*class* schema for this tripartite division of types.[2]

In one respect, however, there was significant, if halting, advance. A fourth category or type eventually received explicit recognition, the entrepreneur. Not that economists had ever accomplished the impossible feat of overlooking the most colorful figure in the capitalist process. The scholastic doctors, at least since the times of St. Antonine of Florence, had distinguished the businessman's *industria* from the workman's *labor.* Seventeenth-century economists had displayed an unmistakable, if inarticulate, understanding of the type. Cantillon was, so far as I know, the first to use the term entrepreneur. But these suggestions petered out without coming to fruition. A. Smith glanced at the type occasionally—he speaks occasionally of the undertaker, the master, the merchant—and, if pressed, would not have denied that no business runs by itself. Nevertheless this is exactly the over-all impression his readers get. The merchant or master accumulates 'capital'—this is really his essential function—and with this 'capital' he hires 'industrious people,' that is, workmen, who do the rest. In doing so he exposes these means of production to risk of loss; but beyond this, all he does is to supervise his concern in order to make sure that the profits find their way to his pocket. J. B. Say, moving along in the French (Cantillon) tradition, was the first to assign to the entrepreneur—per se and as distinct from the capitalist—a definite position in the schema of the economic process. His contribution is summed up in the pithy statement that the entrepreneur's function is to *combine* the factors of production into a producing organism. Such a statement[3] may indeed mean much or little. He certainly failed to make full use of it and presumaby did not see all its analytic possibilities. He did realize, to some extent, that a greatly improved theory of the economic process might be derived by making the entrepreneur in the analytic schema what he is in capitalist reality, the pivot on which everything turns. But he failed to realize that the phrase 'combining factors,' when applied to a going concern, denotes little more than routine management; and that the task of combining factors becomes a distinctive one only when applied not to the current administration of a going concern but to the organization of a new one. In any case, however, he turned a popular notion into a scientific tool.

---

[1] Subgroups were, of course, introduced when desirable. But in dealing with the general pattern of economic theory, we may neglect this fact.

[2] Sismondi was the only other economist of major importance to do the same thing. But he did so only for purposes of simplification, not as a matter of principle.

In Germany, the concept of the entrepreneur was a familiar element of the 'cameralist' tradition. And so was the corresponding term, *Unternehmer,* which the economists of the period continued to use—it occurs, for example, in Rau's textbook. The analysis of the entrepreneurial function developed steadily if slowly, culminating in the work of Mangoldt.[4] How much of it, if anything, is due to influence from Say, I feel unable to tell. But in England this influence shows more clearly. Ricardo, the Ricardians, and also Senior took indeed no notice of Say's suggestion and in fact almost accomplished what I have described as an impossible feat, namely, the exclusion of the figure of the entrepreneur completely. For them—as well as for Marx[5]—the business process runs substantially by itself, the one thing needful to make it run being an adequate supply of capital. But some of the non-Ricardian and anti-Ricardian writers of the late 1820's and the 1830's did take it up, Read and Ramsay—the latter used the term 'master' rather than entrepreneur, though he spoke of enterprise—deserving special mention. The decisive step was taken by J. S. Mill, who brought the term entrepreneur into general use among English economists and, in analyzing the entrepreneurial function, went from 'superintendence' to 'control' and even to 'direction,' which, he admitted, required 'often no ordinary skill.' But this defines the function of management and not anything distinct from mere administration. If this were all, he might as well have been content with the good English term, manager—which was in fact adopted later on by A. Marshall—and have spared himself all regrets about there being no good English word for entrepreneur. A reason why he did not do so was possibly that managers are frequently salaried employees and they do not necessarily share in business risks, whereas J. S. Mill, like all the authors of that period and most authors of the next one, wished to make risk-bearing an entrepreneurial function alongside of 'direction.' But this only served to push the car still further on the wrong track.[6] And there it stuck. There were various attempts at improvement and development during that period and the subsequent one. Substantially, however, J. S. Mill's conception of the entrepreneurial function prevailed throughout the century, which means that, after all, Say's suggestion came to very little. We shall presently return to the subject.

---

[3] Lest the reader feel inclined to read this either into Cantillon or into A. Smith, let me further explain my reasons for believing that Say's formulation should be considered a distinct step in analysis. Cantillon said indeed that the entrepreneur acquires means of production at certain prices with a view to selling at uncertain (expected) prices. This describes one of the aspects of the businessman's activity very well; but it does not describe (or, at any rate, emphasize) its essence. A. Smith considers indeed the case of the capitalist who lends his capital to other people and thus seems to recognize the distinct function of those people who take the trouble and risk of employing it. But the businessman who borrows from the capitalist still remains a vicarious capitalist, i.e. an intermediary between the owner of capital and the labor force; and to provide the latter with tools, means of subsistence, and raw materials is still all he does. It might be said that the distinctive function that Say made explicit is implied both by Cantillon and Smith. But analytic progress—not only in economics—hinges in great part on making things explicit that have been implied or implicitly recognized for ages. A. Smith also knew that we pay for goods because we want them, but this does not make him a marginal utility theorist.

---

[4] See above, ch. 4, sec. 5 and below, ch. 6, sec. 6a. The work marks in this respect the most important advance since Say.

[5] In his case this stands out particularly because he went into so much detail about the process of accumulation. Accumulated capital, with him, invests itself in a wholly automatic manner. All the phenomena and mechanisms in the emergence of mechanized large-scale enterprise that hinge upon the personal element are completely shut out from his range of vision. A famous passage in the *Communist Manifesto* (concerning the 'wonders' that the 'bourgeoisie' has accomplished) seems to contradict this, since mere investment of accumulated capital could hardly be said to be productive of 'wonders.' But this conception of entrepreneurial achievement—for what else could be responsible for the bourgeois miracles?—entirely failed to influence his basic analysis.

[6] Since many modern economists also include risk-bearing among entrepreneurial functions, it may be well to point out at once the objection to the idea. It should be obvious, so soon as we have realized that the entrepreneur's function is distinct from the capitalist's function, that an entrepreneur, when he employs his own capital in an unsuccessful enterprise, loses as a capitalist and not as an entrepreneur. It has been said that if he borrows at a fixed rate of interest, the capitalist being entitled to repayment plus interest irrespective of results, it is the entrepreneur who bears the risk. But this is a typical instance of a very common confusion of economic and legal aspects. If the borrowing entrepreneur has no means of his own, it is obviously the lending capitalist who stands to lose, his legal rights notwithstanding. If the borrowing entre-

(b) *The Agents.* The reader is requested to observe how very short, simple, and natural the step is from the recognition of the three categories of participants in the economic process—landowners, workmen, and 'capitalists'—to a general schema of this process. The categories are characterized by a purely economic trait: they are respectively the suppliers of services of land, of labor, and of a stock of goods that is labeled 'capital.' This seems to settle their role in production and, quite unbidden, the famous triad presents itself, the triad of agents, or factors, or requisites—or instruments (Senior)—of production. And, not less easily, a triad of incomes emerges to correspond to the triad of factors—rents, wages, and 'profits.' Surely nothing could seem more useful and more simple or more obviously in accord with fact to any person not influenced by previous acquaintance with economic controversy. This is the first point about the triad of factors that I want the reader to realize.

The second point to be borne in mind is that the triad is, nevertheless, not popular with modern economists. It established itself, more or less, around the middle of the nineteenth century and took a new lease of life through A. Marshall's sponsorship of it.[7] And it still survives, owing to its handiness in elementary teaching. Beyond this, however, modern economists do not like it particularly: some look upon it as a relic of bygone stages of analysis, a clumsy tool, an encumbrance rather than a help. But for the moment, we are not concerned with this, but with a third point. For reasons quite different from those that motivate the attitude of modern theorists, economists of the period under survey were reluctant to accept the triad, which accordingly conquered but slowly and incompletely—a fact that, considering the obviousness of the schema, calls for explanation. Moreover, examination of these reasons will teach us an interesting lesson about the 'ways of the human mind' in our field.

In Chapter 6 of the First Book of the *Wealth of Nations,* A. Smith decomposed the price of products into three components: wages, rent, and profit. In Chapter 7, these prices are built up again from these same components.[8] In itself, this points strongly enough toward the triad of factors.

---

preneur has means by which to effect discharge of his debt, he too is a capitalist and, in case of failure, the loss again falls upon him as a capitalist and not as an entrepreneur.

[7] Marshall had indeed a fourth factor or agent of production, Organization. But this is only a label for a compound of topics—such as division of labor and machinery—of which business management is only one. It is not an agent in the same sense as are land, labor, and capital.

[8] These are equilibrium prices. As we know, the arrangement referred to embodies A. Smith's manner of recognizing the fact of general interdependence between the elements of the economic system and constitutes one of his greatest merits in the field of pure analysis. But we also know that it was much misunderstood—some critics even saw circular reasoning in it.

But the pointer is completely lost in the argument of Chapter 6. There, laborers, landlords, and capitalists are indeed introduced as participants in the process of distribution, but their shares are not construed as returns from the productive employment of their factors: if not wholly denied, and even if occasionally 'recognized,' [9] this factor-value aspect of distributive shares is brushed aside in favor of quite another aspect. A. Smith, it will be remembered, tries to show how the landlord's and the capitalist's shares are 'deducted' from the total product that 'naturally' is, in its entirety, the product of labor. And this seems to point toward a different conceptual arrangement, which reserves the role of factor of production for labor alone and bars the outlook on the triad of factors in spite of the fact that A. Smith's language on the first page of Chapter 7 is clearly suggestive of it.

A. Smith's exposition has been restated, in the first place, because it anticipates instructively the situation that prevailed in this corner of economic theory throughout the period. Whether under A. Smith's influence or independently, some economists took the line indicated by the one of A. Smith's pointers, and some took the line indicated by the other. But the majority hesitated and compromised, though the tendency was all along in favor of the triad of factors. In the second place, we have started from A. Smith because his exposition illustrates very well the nature of the main obstacle that stood in the way of smooth acceptance of the three-factor schema. In order to see it, we must recall once more that the proposition that labor alone produces the whole product has no empirical content that could be relevant in an analysis of the facts of the economic process: clearly, nobody can maintain that labor is all that is needed in order to produce something, except in a class of cases without importance. But the proposition may have 'meta-economic' meaning of an ethical color and it agrees well with the emotional propensities and the political doctrines of sponsors of the interests of labor who, like A. Smith, loved to declaim about the laborer who produces everything for everybody and himself 'goes in rags.' They thought that they were gaining a point for labor by clinging to that doctrine, and they were confirmed in this childish belief by the no less childish belief of many sponsors of the triad that setting up land or capital as factors of production was gaining a point for landlords or capitalists.[10] They failed to see that their ethical philosophies and political doctrines were logically irrelevant for the explanation of economic reality as it is. In other words, they failed to see that all that matters for this purpose is the simple fact that, in order to produce, a firm needs not only labor but all the things that are included in land and capital as well, and that this is all that is implied in setting up the three factors. In still other words, they had not yet a clear conception of the distinctive purposes of analysis—have we?—and *of what is and what is not relevant to the analytic purpose.* It will be realized therefore that to see this distinctive purpose and to perceive that the three-factor schema served it in a simple way was, under the circumstances, not quite so easy as one might infer from its obviousness and that hence its adoption spelled considerable analytic merit after all.

---

[9] Thus, A. Smith described the gross revenue of society as 'the whole produce of their land and labour' (beginning of ch. 2, Book II).

[10] I do not deny, of course, that slogans for popular consumption may be derived from either analytic set-up. To that extent—that is, if meant for the sole purpose of taking in slow-witted people—neither was childish. Only the honest belief was childish that any analytic arrangement about factors of production could *in good logic* strengthen the political use either for or against the claims of their owners. That this is not so has been pointed out repeatedly in this book: even if there were any sense in maintaining that, e.g., land produces everything, this would not constitute any reason why the returns from it should go to its owners.

There is, however, another aspect to the matter. If one accepts a labor-quantity theory of value, either in Ricardo's or in Marx's manner (see below, ch. 6, sec. 2a), the three-factor schema, which we have been commending for its simplicity, meets with *analytic* difficulties that are quite independent of any philosophies. For the distributive shares must be paid from prices of products that, owing to the presence of claimants other than labor, cannot in general be proportional to the quantities of labor embodied in those products. A new problem therefore arises concerning the manner in which those other claims are satisfied. And in attempting to solve *this* problem, we find the triad of factors that puts these factors all in fundamentally the same logical position very inconvenient to handle:[11] from *this* standpoint the mere fact that all agents are equally 'requisite' cannot any longer be regarded as decisive. Note this interesting fact: from the standpoint of any theory of value other than the labor-quantity theory, this problem appears as a choice example of a spurious problem, that is, a problem that owes its very existence to defective analysis and disappears, without any trouble, if the defective element, in this case the labor-quantity theory of value, be removed; but from the standpoint of the labor-quantity theory of value, the problem in question becomes the most important of all, the problem the solution of which must reveal the innermost secret of capitalist society. Marx had therefore plenty of reason to rise in wrath against the triad of factors and to condemn it as a piece of vile apologetics that, reducing colorful struggles of social classes to colorless allocations of returns to co-operating factors, emasculated capitalist reality.[12] Sometimes,

[11] James Mill and McCulloch tried to do this with very indifferent success.

[12] Conceiving of economic analysis as an element in social evolution—and theories other than his as the fog that rises from it—Marx, as stated above, was of the opinion that, after Ricardo, 'bourgeois economics' had entered a stage of decay along with the society that produced it. It is not without interest to ask what the facts were he took for manifestations of this decay. The first we know already: it was the refusal of 'bourgeois' economics to couch its analysis in terms of social classes. The second, related to the first, was precisely the increasing tendency to adopt the three-factor schema. The third was the tendency to assert that the economic process, however much given to stalling under the impact of 'disturbances,' was yet free, in its pure logic, from inherent hitches. Marx took this for another piece of 'whitewashing' though, from another standpoint, it was the natural consequence of improved analysis. The fourth was the tendency to replace what Marx considered to be profoundest truth by a description of the surface phenomena of business practice as they appear to the business-

the task of analysis is rendered difficult by the nature of its problems—wave mechanics is a good example. Sometimes the difficulties are not in the things but in our own minds.

As soon as this is understood, we can deal very briefly with the facts of the case. The aversion to the triad schema that was due to philosophical or political or emotional causes gave way eventually and in the end asserted itself merely in verbal concessions. The obstacle of the labor-quantity theory was, of course, next to insuperable for Ricardo himself and for the Ricardian socialists, including Marx. But it was overcome by the non-Ricardian and anti-Ricardian theory of the 1830's—which shows again that the Ricardian teaching was really in the nature of a detour. On the Continent, Say—possibly following Turgot's lead—established the triad schema[13] and the practice of dealing, both in the theory of production and in the theory of distribution, with the 'services' of the three factors on the same footing. In England, Lauderdale was the first major writer to set up capital as a distinct factor. Malthus placed no emphasis upon the triad but his theoretical set-up implies it. Torrens, Read, and Senior, especially the last, are the most important of the economists who helped it toward anchorage in English economics.[14] J. S. Mill, finally, adopted it in substance but hesitatingly and without going through with it—in a way that mirrors the actual doctrinal situation very well. He started like Petty with two 'requisites' of production, a felicitous term that disarms unintelligent criticism by avoiding any suggestion to the effect that 'agents' might be morally entitled to 'rewards.'[15] Then he noticed the fact that the economic process of every period also depends on the stock of goods that is available at the beginning of the period *which is all that is implied in setting up 'capital' as a distinct factor*. And so he recognized capital as a factor but distinguished it from the other two, the two 'original' ones.[16] Senior had spoken of capital as a 'secondary' agent in contrast to the two 'primary' ones. There is in fact point in maintaining that capital is a 'factor with a difference.' For, if capital is goods, it raises problems of depreciation and renewal that the other two factors do not raise. And if capital is so defined as to include wage goods, it is not quite on a par with land and labor but stands to them, so far as the wage goods are concerned, in a relation that is peculiar to it. But J. S. Mill did not go much further than this. Though he did recognize occasionally that in this schema the rent of land enters or does not enter into price and cost exactly as do wages, he yet refused to put land quite on a par with labor. He

---

man. It is for the reader—and an excellent exercise it would be—to make up his mind on these points *now*.

[13] He also generalized 'land' into 'natural agents.'

[14] And in spite of Say's priority and in spite of the fact that we moderns do not think very highly of it, there was considerable merit in this around 1830.

[15] The term Requisite is, so far as I know, due to James Mill, who has labor and capital, however, instead of labor and land. J. S. Mill uses also the term Agents.

[16] If we wished to be nasty, we could quote him to the effect that he started with two factors and, after prolonged discussion, 'reduced' these two factors to three (Book 1, ch. 1, § 1 and ch. 7, § 1).

therefore clung, officially as it were, to the Ricardian theory of rent, although it was quite superfluous for him.[17] And capital remained stored-up labor for him, as it had been for James Mill, although from the standpoint of his schema and if he wished to 'resolve' capital into something else, he should have 'resolved' it into stored-up services of labor *and land*.[18]

To sum up: the question what is and what is not to be 'recognized,' by the analyst, as an agent of production is a mere question of analytic convenience and efficiency. As such, however, it is very important, for the way in which a writer answers it will, to a considerable extent, determine his schema of the economic process and the formulation of the problems to be solved. At an early stage of analysis, the triad of *agents* suggests itself primarily because it links up nicely with the three categories of participants in the economic process that are derived from the layman's picture of society. But it so happens that the triad also makes economic sense because it presents a complete list of the requisites of physical production, the items of which are both nonoverlapping and distinguished by economically relevant characteristics. Therefore, it makes a useful basis to start from. J. B. Say seems to have been the first to realize this fully. But most of the economists of the period did not look at the matter in this light. They believed that when they were deciding what to 'recognize' as an agent, they were dealing with momentous real problems of analysis and, still more important, of social justice. Hence we find widespread reluctance to adopt the triad, which was reinforced, in some cases, by a theory of value that did not work well with it and by the fact that the role of capital in the productive process does display certain traits that are not shared by the two 'original' or 'primary' agents. And so one-factor schemata and two-factor schemata survived throughout. Moreover, even writers who in fact adopted the three-factor scheme displayed a tendency to make verbal concessions to the other two[19]—which further obscures the situation.

(c) *The Model.* In every scientific venture, the thing that comes first is Vision. That is to say, before embarking upon analytic work of any kind we must first single out the set of phenomena we wish to investigate, and acquire 'intuitively' a preliminary notion of how they hang together or, in other words, of what appear from our standpoint to be their fundamental properties. This should be obvious. If it is not, this is only owing to the fact that in practice we mostly do not start from a vision of our own but from the work of our predecessors or from ideas that float in the public mind. We then proceed to conceptualize our vision and to develop or correct it by closer examination of facts, two tasks that of necessity go together—the concepts we possess at any time and the logical relation between them suggesting further factual investigation and further factual investigation suggesting new concepts and relations. The total or 'system' of our concepts and of the relations that we establish between them is what we call a theory or a model. We have had ample opportunity to observe how difficult a task conceptualization is in the early stages of analytic effort, chiefly because the scientific fraternity takes time to learn, by a process of trial and error, what is and what is not important in an 'explanation' of the phenomena envisaged. In economics, particularly, there are many inhibitions to overcome before the nature of the analyst's task can be clearly understood. But model building, that is, conscious attempts at systematization of concepts and relations, is more difficult still and characterizes a later stage of scientific endeavor. In economics, efforts of this kind date, substantially, from Cantillon and Quesnay. In the period under discussion, a model evolved from the Cantillon-Quesnay pattern that, since we already know the actors and the agents that figure in it, may be briefly described as follows. Consideration of details will be deferred to the next chapter.[20] Moreover, comments on the 'classic' schema of economic evolution will be deferred to the next section. In this section I shall present the 'classic' schema of a stationary process only—a schema which, in this respect, was much like that of Quesnay.

---

[17] The specifically Ricardian element in the theory of rent was logically superfluous for him because mere 'requisiteness' of land plus its scarcity is all that is needed to explain the price of its services. Yet he commits himself to the Ricardian view of rent, e.g., in the last sentence of § 2, ch. 2, of Book III.

[18] Let us notice at once that this 'resolution' of capital goods, e.g., a machine, involves *two* problems: first, the 'resolution' of the machine into the factors that enter into it and include services of other capital goods; second, the 'resolution' into land and labor only (or, with Marx, into labor only). In the next period it was especially Böhm-Bawerk and, following him, Wicksell who used and propagated the 'resolution' into land and labor.

[19] Such a verbal concession that veils a man's acceptance of the triad is instanced by the turn of phrase that capital increases the productivity of labor (or that its function consists in making labor more effective). This *seems* to point toward a one-factor theory by confining the honorific quality of productivity to labor alone but actually does, so far as explanation of facts is concerned, exactly what 'recognition' of capital as an agent of production is meant to do.

From A. Smith on, most of the English 'classics' used the term Stationary State. But this stationary state was an actual condition of the economic process which they expected to materialize sometime in the future. Taken in this sense, the subject of the stationary state belongs in the next section. Here we are concerned with a different kind of stationary state, namely, with a stationary state that is not a future reality but only a conceptual construct or tool of analysis that serves to isolate, for the purposes of a preliminary study, the group of economic phenomena that would be observable in an unchanging economic process. The first to recognize explicitly the methodological importance of doing this was J. S. Mill. But Marx, whose schema of Simple Reproduction (*Capital*, vol. 1, ch. 23) is the schema of an economic process that merely reproduces itself in time, went much more deeply than Mill. All other writers, however, including A. Smith and Ricardo, actually used that tool but, not being aware of the fact that they were using any particular device of this kind, they used it in a haphazard and unsatisfactory manner. This point being both important and somewhat difficult to understand calls for additional comment.

---

[20] This procedure entails the disadvantage that certain concepts will have to be used before they have been fully explained. No serious inconvenience will, however, arise from this.

We have repeatedly had the opportunity to advert to the slow development, not completed within the period under discussion or even within the next one, of the notions of economic (or social) statics and dynamics. J. S. Mill, who as we have seen probably took them from Comte and used them in his logic, defined statics as the theory of 'the economical phenomena of society considered as existing simultaneously' (*Principles*, Book IV, ch. 1, § 1). This definition, by itself, might pass muster as an anticipation of the modern definition (Frisch). Statics as thus defined pivots on the concept of (stable or unstable) equilibrium that appears in Mill and in the 'classic' literature generally, for example, in the garb of such constructs as the 'natural' or 'necessary' prices. But a little later, we learn that in the passage quoted he did not really think of the statics that is defined by his wording or, rather, that he confused it with 'the economical laws of a stationary and unchanging society.' As we shall see more clearly later on, these are different things: we can study a changing process by means of a static method (comparative statics, see below, Part IV, ch. 7, sec. 3a) and an unchanging process by means of a sequence analysis of the kind which Sismondi occasionally used, and which relates economic quantities that belong to different points of time—i.e., by means of a dynamic theory in the sense of Frisch. Mill, following Comte, understood by dynamics something altogether different, namely, the analysis of those forces that produce fundamental change in the long run—the kind of thing we shall discuss in the next section. All this is confusing enough. But we must add a final element to the confusion. In addition to speaking of a static *theory* and of a stationary *state*, which is an analytic tool, Mill also, like Ricardo, expected the economic process to settle down, at some future time, into a stationary state of a special kind that will not be an analytic device for facilitating the study of a nonstationary reality but will be itself a reality. I repeat that, in all this, Mill did no more than to make explicit what everybody fumbled for.

Some of the fundamental features of the 'classic' model or models of the stationary process may be thus described in Ricardo's words (*Principles*, ch. 31). Suppose that a capitalist 'employs a capital of the value of £20,000' and 'that profits are 10 per cent.' Of this capital, £7000 are 'invested in fixed capital, viz. in buildings, implements, etc. etc.' and 'the remaining £13,000 is employed' as wage capital [21] 'in the support of labour.' 'Each year the capitalist begins his operations by having food and necessaries in his possession to the value of £13,000 [plus another quantity of the value of £2000 destined for his own consumption, J. A. S.], all of which he sells in the course of the year to his own workmen for that sum of money, and, during the same period, he pays them the like amount of money for wages: at the end of the year, they replace in his possession food and necessaries of the value of £15,000, £2000 of which' he then consumes himself in the following year[22]—a piece of sequence analysis that is certainly the last word in simplicity—which is why I refrain from elucidating it either by a system of equation or by a *tableau* of the Quesnay type.[23]

---

[21] Ricardo wrote 'circulating capital,' but see below, ch. 6, sec. 5b.

Now, first, one feature of this model was generally accepted throughout the period, by Marx not less than by Say. This was the physiocrat notion, which it embodied, that the fundamental flows of goods (and money) that constitute the economic process consist of a flux and an (augmented) reflux of 'advances.' Yet, unlike the physiocrats, the 'classics' made the capitalists the sole source of these advances, and the value of the *goods* advanced swelled in the industrial process instead of in agriculture only. Nevertheless, it was substantially the old idea of Quesnay as it had already been transformed by Turgot. I cannot emphasize too strongly that this was a particular way of *interpreting* the economic process and not at all directly suggested by the practice of life: in practice, the employer 'hires' the workman—or he may be said to 'buy' the latter's services—but he does not advance anything to him. Moreover, this interpretation means more than recognition of the trivial facts that whatever is being consumed must have been produced before; or that society at any moment always lives on the past and works for the future; or, finally, that initial stocks are always among the data we must start from. J. B. Clark's theory of the synchronized process or, for that matter, Walras' system (both discussed below, Part IV, ch. 7) proves sufficiently that these facts do not force us to make them the pivots of our analysis. But if we do make them the pivots, then a number of consequences suggest themselves that are not avoided simply by refusing to recognize them. If 'capitalists' actually advance labor's real income and if this is to mean more than a monetary arrangement, discounts and 'abstinence' will have to be admitted among the essentials of the economic process whether we like them or not:[24] that is, no analysis of production and consumption will be complete that does not take account of them in one way or another. This is important enough to justify a distinctive label for all analytic patterns that do work with the notion under discussion. We may call them *advance economics* and distinguish them from *synchronization economics*, that is, all analytic patterns that do not in a stationary process assign any fundamental role to the fact that what society lives on at any given moment is the result of past production, on the ground that, once a stationary process has been established, the flow of consumers' goods and the flow of productive service are synchronized so that the process works *as if* society did live on current production.

---

[22] Ricardo neglects, of course, the wear and tear of the machines, etc. This could be easily avoided, but we shall do the same thing. The £2000 must be consumed each year or else the process would not be stationary.

[23] But, in spite of its gauntness, the model we took from Ricardo will still serve two purposes that may be of some help to the reader. First it will illustrate what dynamic analysis in the modern sense is and in what it differs from the kind of investigation that J. S. Mill denoted by Dynamics. Second, it will explain what sounds like a paradox even to some economists of today, viz., how it is possible to treat a stationary process dynamically. This consists simply in describing such a process in terms of quantities that belong to a sequence in time or in terms of relations that link quantities that belong to different points of time. The particular form of dynamic analysis which this model displays is, for obvious reasons, often called Period Analysis.

[24] Talk about exploitation may cover up this state of things but cannot alter it. If I were asked what I consider the easiest method for upsetting Marx's theoretical structure, I should certainly answer: start from Marx's admission that capitalists advance wages and develop the logical consequences of this admission. I should add, of course, that this is the answer to the question what is the easiest, not to the question what is the most profound, set of moves for the anti-Marxist to make.

Second, we may as well introduce another classification of analytic patterns ('theories'), though its practical usefulness is in the analysis of growth rather than in the analysis of stationary states. No economist has ever denied, of course, that, like every other engine, the economic engine is given to stalling, besides being sensitive to disturbance by factors external to itself. But economic models differ according to whether they are or are not built on the assumption that the economic engine has or has not an *inherent* tendency to develop hitches (merely by working normally and according to design), which then make it stall or stop working normally and according to design. The various forms of underconsumption theories of crises that we shall discuss later on may serve as examples: they all of them hold that, because of oversaving or other reasons, the economic system, as it goes on functioning, develops strains and stresses by virtue of its own design or logic, for example, the strain or stress that—really or supposedly—shows in the impossibility of selling the products it is capable of producing at prices that will cover costs. With apologies, I introduce the term *hitchbound* for models that do recognize the existence in the economic system of such inherent tendencies to stall, and the term *hitchless* for models that do not. For the moment, all we get from an application of this distinction is the statement: all the models of stationary processes that were ever constructed are hitchless. Marx, for example, makes this very clear—hitches do not occur in his schema of Simple Reproduction; they enter his picture only with Accumulation.

A few comments may be useful. To begin with, though all economists do recognize the propensity of the economic engine to stall on any number of provocations and its sensitiveness to the impact of external disturbance, there is still room for disagreement as regards the importance of this propensity to stall and sensitiveness to disturbance, in particular as to the importance of both, relatively to the importance they would have in a planned economy. These questions may well make all the difference in an appraisal of the relative efficiency of different forms of economic organization. Next, let us notice that, precisely because of this, there is no question of apologetics or 'whitewashing' involved in constructing a hitchless model. For the economist who constructs such a model may still have so high an opinion about the sensitivity of the economic system he wishes to describe that he may, because of this sensitivity, rate its efficiency lower than does another economist who prefers a hitchbound model but has no such high opinion about the importance of the hitch. Malthus' model of economic growth was hitchbound. But this did not make him a 'planner.' Finally, observe that the analyst's choice between constructing a hitchbound and constructing a hitchless model is to some extent a question of mere analytic convenience. Two economists may entertain exactly the same opinion about something that both of them recognize as a stress. Nevertheless, the one may think it more useful to build a hitchless model first and then superimpose the stress, and the other may think it more useful to introduce the stress, as it were, on the groundfloor, and include it in his model from the first so that he gets a hitchbound model. The same man may do the one for some purposes and the other for other purposes. It is only our inability to divorce research from politics, or our suspicion, all too often justified, that the other fellow cannot analyze with single-minded devotion to truth, which makes problems and party issues out of decisions that do not excite anyone in more fortunate fields of research.

Third, the model from which we started may be complicated in various ways without losing its fundamental simplicity. Thus, we can easily introduce current production of producers' goods and investigate the simple conditions for equilibrium that exist between the various departments of production.[25] Also, we can easily introduce servants, physicians, teachers, and so on. More important, the reader may wonder what has become, in that model, of the third class of actors, the landowners. Why they do not figure in Ricardo's text will become clear presently. Marx treated them as a sort of appendage to the 'capitalists.' The 'capitalists' employ labor and extort from it Surplus Value. But this surplus value is not all Ricardian profits. The 'capitalist' must share his loot, the surplus value, with the landlords. Thus, in a second act of the drama of distribution, the surplus value is split into profits and rent, both of which are therefore simply parts of a unitary exploitation gain. Everybody not completely blinded by indoctrination will, however, realize immediately that, so far as description of fact and not agitatorial phraseology is concerned, this comes to the same thing as saying that the capitalist hires services of land exactly in the same sense in which he hires services of labor. In fact, all we need to do in order to arrive at this result is to ask the question why landlords are in a position to prey upon the 'capitalist's' loot. The only answer is that the services of land, also, are requisites of production. As soon as we realize this not very recondite truth, we arrive at what, to any unbiased mind, must seem to be the most natural view to take: the landowners should enter the model of the stationary process, along with labor, as another class of owners of productive services, which, at the beginning of (or during) each period, they stand ready to exchange for the income goods that the 'capitalists' were supposed to possess.[26] This should be extended, of course, to the 'capitalists' (or whoever the people are) who own the nonwage capital.

---

[25] Marx, more directly inspired by Quesnay than was any other economist of his time and perceiving more clearly the importance of such research, tried to construct tableaus or reproduction schemata of his own, starting from Quesnay's *tableau*. Technical handicaps prevented him from getting very far either in this or in the attempt to replace it by arithmetical or algebraic equations. However, *in magnis voluisse sat est* and he saw more intuitively than he was able to express. His efforts naturally centered on the case of 'extended' rather than of 'simple' reproduction. But he developed the condition of stationarity all right, and also the condition of equilibrium between the two departments of consumers' goods and producers' goods production. The interested reader finds all he needs in P. M. Sweezy's *Theory of Capitalist Development* and in its Appendix by Shigeto Tsuru.

Fourth, as our discussion of Agents must have led readers to expect, the frame provided by the model under study was filled in, not by one but by two theories (or types of theories) of production and distribution, which were but very imperfectly welded in J. S. Mill's mongrel performance. This was because the triad of agents and returns was gaining ground so slowly—we know the reasons why—that types of analysis that were distinctly more primitive not only survived but also prospered.

On the one hand, then, we have the analysis that is associated, primarily, with the names of Turgot and Say; partially, hesitatingly, and mixed with incompatible elements, it was also outlined by A. Smith. It accepted the triad of agents and returns in its fullest and deepest meaning. Let me restate this meaning. Production in the economic sense of the term[27] is nothing but a combination, by purchase, of requisite and scarce services. In this process, each of the requisite and scarce services secures a price, and the determination of these prices is all that distribution or income formation fundamentally consists in. Thus the process effects, in one and the same series of steps, production in the economic sense and, through the evaluation of productive services incident to production, also distribution or the formation of incomes. Thus, in this schema, capitalist production and distribution cease to be what they would be in a socialist community, namely, two distinct processes: we behold but one process of choices and evaluations of which production and distribution are merely two different aspects. And all types of incomes are by this schema explained on one and the same principle, the principle of pricing the services of co-operating factors. The analytic task of showing how this principle, so obvious in the case of consumers' goods or their services, may be made to apply also to the case of producers' goods or their services, was not clearly discerned, let alone accomplished before the rise of the theory of imputation in the next period (see Part IV, ch. 5, sec. 4a), except perhaps by a few forerunners, such as Longfield and Thünen. But the fundamental thesis, that the production-distribution process of capitalist society is in the last analysis a web of exchanges, for one another, of productive (or directly consumable) services—the employing entrepreneur acting as an intermediary—stands out with unmistakable clearness in Say's *Traité*. Among leading English authors, Lauderdale, Malthus, and Senior came more or less near to grasping this idea. But only Say made something like a success of it. It is nothing short of pathetic that, owing to a complete lack of understanding on the part of opponents and owing to complete ignorance of even the most elementary mathematical tools on the part of exponents, this promising start not only was left to hibernate for decades but also acquired a reputation for superficiality and sterility.

---

[26] This curious idea, according to which capitalist employers are supposed to hold cabbages and shoes, which they sell to their workmen, must be viewed as a measure of simplification designed to bring out essentials and meanings that underlie the treacherous mass of surface phenomena in a monetary economy. 'Capitalists' who are not themselves producers of food and necessaries are supposed to acquire these from the 'capitalists' who are. Even if it should be granted that this schema brings out the essentials correctly, we have still to observe that it neglects so many intermediate steps and draws together the essentials so closely—another example of this is the 'classic' theory of saving and investment—that the possibility of deriving practical conclusions from such a theory becomes questionable.

[27] It is highly characteristic of the difficulties most authors experienced in the task of conceptualization that the large majority kept on defining production technologically. They philosophized about man's inability to 'create matter' and his ability to displace it and to change its forms in useful ways and other completely irrelevant things. Say's phrase to the effect that production produces utilities pointed in the right direction, but much more important was his emphasis upon the combination of services in connection with his definition of entrepreneurial activity.

On the other hand, we have the type of analysis of which the Ricardian detour is the outstanding example. It would of course be an exaggeration to say that Ricardo was entirely blind to the aspect of the economic process described above. He had glimpses of it now and then, and Professor Knight went perhaps too far if he accused Ricardo of not having seen the problem of distribution as a problem of valuation *at all*.[28] But it is true that Ricardo failed to see the explanatory principle offered by the valuation aspect. This failure is intimately related to a peculiarity of the Ricardian work that is essential for understanding him and proves better than does anything else that this work constitutes in fact a detour and falls out of the historical line of economists' endeavors.

For A. Smith, A. Marshall, and ourselves, the factors that explain the size and rate of change of the Social Product or National Dividend or Total Net Output are of primary significance. This was not Ricardo's view. On the contrary, in his preface to the first edition of the *Principles*, he tells us: 'To determine the laws which regulate this distribution [of total product between landowners, capitalists, and laborers, J. A. S.] is the principal problem in Political Economy.' That is to say, he all but identifies economics with the theory of distribution, implying that he had little or nothing to say about—to use his language—'the laws which regulate total output.' This is a strange view to take, though it must be added at once that he did not always adhere to it, as his chapters on foreign trade and on machinery show. It enables us, however, to state the fundamental problem Ricardo wanted to solve in terms of an equation between four variables: net output equals rent plus profits plus wages (everything measured in Ricardian values, see below, ch. 6, sec. 2a). And it does still more for us. It rids us of one of these four variables. For, since we have nothing to say about total net output, we can accept its amount, whatever it is, as a datum. So we really start with an equation that contains only three variables. But one equation in three variables is still a hopeless business. Therefore, Ricardo (ch. 2) places himself on a margin of agricultural production where rent is zero. Observe carefully what this means for Ricardo's analytic set-up. By numberless writers the West-Ricardo theory of rent has been discussed in isolation, and with nothing but the question in mind whether it was 'right' or 'wrong.' This question is completely pointless. The West-Ricardo theory of rent cannot be discussed in isolation, that is, without reference to the whole of the West-Ricardo system. It is within this system only that it acquires analytic meaning and, in fact, owing to Ricardo's inability to deal with systems of simultaneous equations, imposes itself. Outside of the West-Ricardo system considered as a whole, it has very little meaning and is hardly worth bothering about.

---

[28] See F. H. Knight, 'The Ricardian Theory of Production and Distribution,' *Canadian Journal of Economics and Political Science*, vol. I, February 1935. But Knight supported his indictment effectively by a quotation from a letter of Ricardo's to McCulloch to the effect that 'the proportions in which the whole produce is divided between landlords, capitalists and labourers . . . are not essentially connected with the doctrine of value' (ibid. p. 6n.). This is not true even from Ricardo's own standpoint. [Substantially this same footnote appears above, sec. 3. J. A. S. had taken out this section (5) for revision (his notes indicated dissatisfaction with the looseness of the argument) just before his death.]

Let us go on. That theory of rent having fulfilled its only purpose, which is to get rid of another variable in our equation, we are left, on the margin of production, with one equation and two variables—still a hopeless business. But, so it occurred to Ricardo, wages are not really a variable either, at least not within that equation. He thought he knew, from external considerations, what they will be in the long run: here the old Quesnay theory comes in, reinforced by Malthus' law of population—the wages will be roughly equal to what is necessary to enable 'the labourers, one with another, to subsist and to perpetuate their race without either increase or diminution.' And so we reach the blessed goal at last: profit, the only variable left, is determined too. Call this patchwork ingenious, if you so please, but do not deny that it is patchwork—and rather primitive patchwork at that.

Marx's schema is open to a similar objection.[29] He also eliminated rent from the fundamental problem, though in a different way. His equation of distribution, in terms of Marxist values, then reads: net output equals wages plus surplus. Again we can take the net output as a datum. And again the surplus is a residual, the determination of which depends upon the external considerations that determine wages.

J. S. Mill's system, on the contrary, absorbed enough of the Say conception—and in addition was sufficiently helped by Senior's notion of abstinence—to be free from any such objection, and it offered all the elements of the complete model that Marshall was to build. But he retained so many Ricardian relics that there is some excuse for Jevons' and the Austrians' not seeing that they were developing his analysis and for believing instead that they had to destroy it.

---

[29] On Marx's elimination of rent from the final problem, see above, ch. 1, sec. 4; on his equation of distribution in terms of Marxist values, see below, ch. 6, sec. 6g.

6. The 'Classic' Conception of Economic Development

I have tried to explain above (Part I, ch. 4, sec. 1d) the meaning and role of what I have called Vision—that first perception or impression of the phenomena to be investigated which factual and 'theoretical' analysis, in an endless relation of give and take, then work up into scientific propositions. But when we are concerned with nothing more ambitious than to formulate the way in which —on the plane of pure logic—economic quantities 'hang together,' that is, when we are concerned with the logic of static equilibrium or even with the essential features of a stationary process, the role of Vision is but a modest one—for we are really working up a few pretty obvious facts, perception of which comes easily to us. Things are very different when we turn to the task of analyzing economic life in its secular process of change. It is then much more difficult to visualize the really important factors and features of this process than it is to formulate their modi operandi once we have (or think we have) got hold of them. Vision (and all the errors that go with it) therefore plays a greater role in this type of venture than it does in the other. This may be illustrated by the Stagnationist Thesis of our own time, that is, the notion that the capitalist system has spent its powers; that the opportunities of private enterprise are giving out; that our economy is, amid convulsions, settling down to a state of Secular Stagnation or, as some prefer to call it, Maturity. No doubt facts and arguments have been collected in order to establish this notion, which has also been embodied in theoretical models. But it should be obvious that these facts and arguments rationalized a pre-existing vision or impression which they would have been powerless to create, if for no other reason, because the relevant observations extend over a period that is much too short and was much too much under the influence of clearly abnormal events to warrant any conclusions or predictions of that kind. Economists' visions were in no better case a century or so ago. We shall consider three types of vision of the economic future of humanity that the writers of the period under survey tried to formulate and to establish. In other words, we shall consider three types of theories of economic development.

The first type, associated primarily with the names of Malthus, West, Ricardo, and James Mill, fully justifies their being labeled 'pessimists.' Its well-known features were: pressure of population, present already but still more to be expected; nature's decreasing response to human effort to increase the supply of food; hence falling net returns to industry, more or less constant real wages, and ever-increasing (absolutely and relatively) rents of land. We are now not concerned with the manner in which these 'classics' gave analytic effect to this vision of theirs, that is, with the manner in which they formulated their 'laws' of population, decreasing returns in agriculture, and so on.

and with the analytic use they made of them. To this we shall attend in the next chapter. Here we are concerned only with what they thought they *saw*, that is, with the vision that was at the back of their analysis—or, if you prefer, with their preconceptions.

The most interesting thing to observe is the complete lack of imagination which that vision reveals. Those writers lived at the threshold of the most spectacular economic developments ever witnessed. Vast possibilities matured into realities under their very eyes. Nevertheless, they saw nothing but cramped economies, struggling with ever-decreasing success for their daily bread. They were convinced that technological improvement and increase in capital would in the end fail to counteract the fateful law of decreasing returns. James Mill, in his *Elements*, even offered a 'proof' for this. In other words, they were all stagnationists. Or, to use their own term, they all expected, for the future, the advent of a stationary state, which here no longer means an analytic tool but a future reality.

Apparently, J. S. Mill was in better case. He dropped all 'pessimism,' and he was even intelligent enough to realize that there was no reason to look upon the future of the masses 'as otherwise than hopeful.' However, this was only because he believed—as other Malthusians such as Chalmers had believed before him—that mankind was learning the Malthusian lesson and was about to restrict propagation voluntarily so that the race between capital and population would be won by the former. In this he proved himself a better prophet than did others. But he had no idea what the capitalist engine of production was going to achieve. On the contrary, toward the end of his life (around 1870) he really became a stagnationist in the modern sense, believing that the private-enterprise economy had pretty much done what it was able to do and that a stationary state of the economic process was near at hand. But there is this difference between him and our own stagnationists. He did not, as A. Smith and Ricardo had done, view the stationary state with misgivings (*Principles*, Book IV, ch. 6), because he had eliminated the bogey of overpopulation. But neither did he share the modern stagnationist's misgivings, because he did not fear the bogey of underconsumption. To him the stationary state looked rather comfortable—like a world without 'bustle' (his term) in which a philosopher like himself would not mind living and in which there would be moderate prosperity (or better) all round.[1] The question, whether the social structure of capitalism could persist in circumstances in which the main function of the capitalist entrepreneur was being lost, we may answer for him by saying that he visualized the advent of the stationary state as a very gradual process so that institutions and minds would have no difficulty in making the currently necessary adjustments.

In agreement with all the English 'classics'—perhaps we might say, with the spirit of his age—he greatly underrated the importance in economic development of the element of personal initiative and, correspondingly, he greatly overemphasized the importance of mere increase in physical producers' goods. And in this again, he overemphasized the importance of saving.[2] Accepting the Turgot-Smith theory of the investment process, he took it for granted that the important thing was to have something to invest: the invesment itself did not present additional problems either as to promptness—it was *normally* sure to be immediate—or as to direction—it was sure to be guided by investment opportunities that were equally obvious to all and existed independently of the investing man.[3] Saving, then, was the powerful lever of economic development. And it never created obstructions; the saving act itself did not, since the sum saved was immediately spent on productive labor; the resulting expansion of productive capacity did not, since products of correctly planned production were always capable of being sold at cost-covering prices.[4] To use our own term, J. S. Mill's schema of economic development, like Say's, was essentially hitchless. Malthus' and Sismondi's schemata are examples of hitchbound ones, the hitches arising in both cases not so much from saving per se, but from the resulting increase in productive capacity. Ricardo's also was hitchbound, but for another reason, namely, the reason enshrined in his interpretation of the law of diminishing returns.

---

[1] This stationary state was a state of a peculiar kind and did not conform to the definition given above. It did not quite exclude technological progress or increase in capital. It was really stationary with respect to population only, it being assumed that this would cause everything to go on more quietly.

The second type of vision of the economic future—the 'optimistic' type—can be best illustrated by such names as Carey and List. Whatever we may think of the virtues of their technical analysis, at least they did not lack imagination. They felt intuitively that the dominant fact about capitalism was its power to create productive capacity, and they *saw* vast potentialities looming in the near future. With less imagination but with plenty of sound judgment, the majority of economists on the Continent refused to share the 'pessimism' of the Ricardians and of Malthus. At least, most of them watered it down. But beyond this, it was natural for those who more or less followed Say's lead so far as technical theory was concerned to realize that neither facts nor analysis were bearing out the Ricardian vision. These were called 'optimists' and, partly but not wholly under Marxist influence, there grew up a tradition to despise them as shallow. This view is in fact historically associated with many writers—the Bastiat type—who fully deserve to be so called. But in itself this 'optimism' was the result of both a vision and a theory that were more correct than those of the 'pessimists': the degree of truth of a doctrine is by no means always positively correlated with the ability of its exponents.[5]

---

[2] Of course we may define saving in such a way as to make that statement meaningless. But I mean by saving (or thrift) the distinctive phenomenon we all know (unless we are too familiar with the economic theory of the 1930's) and therefore consider it as a factor in the process of the accumulation of physical capital goods. My statement then means that J. S. Mill, like all the authors that followed the Turgot-Smith line, was at fault in believing that thrift was the all important (causal) factor in that process.

[3] This mechanistic view, too, was an important element in the economic *Weltbild* of the 'classics.' They were entirely unaware of how great a part of capitalist reality they thereby suppressed in silence.

[4] The latter proposition is more delicate to handle than J. S. Mill and the economists of his time and line realized. But its opponents were below and not above the limited truth it asserts. Also, though in a particularly narrow way—through saving alone—Mill thus did recognize the most obvious of all truths about capitalist development, viz., that, by virtue of its logic, it tends to raise the standard of life of the masses.

The third type of vision of the economic future and of corresponding theories of economic development will be represented by Marx alone. Based upon a diagnosis of the social situation of the 1840's and 1850's that was ideologically vitiated in its roots,[6] hopelessly wrong in its prophecy of ever-increasing mass misery, inadequately substantiated both factually and analytically, Marx's performance is yet the most powerful of all. In his general schema of thought, development was not what it was with all other economists of that period, an appendix to economic statics, but the central theme. And he concentrated his analytic powers on the task of showing how the economic process, changing itself by virtue of its own inherent logic, incessantly changes the social framework—the whole of society in fact. We have already dwelt on the grandeur of this conception; we shall briefly discuss its analytic aspects below.

Only two points can be mentioned here. First, nobody—not even the most ardent of optimists with whom Marx had this point in common—had *then* a fuller conception of the size and power of the capitalist engine of the future. With a quaint touch of teleology, Marx said repeatedly that it is the 'historical task' or 'privilege' of capitalist society to create a productive apparatus that will be adequate for the requirements of a higher form of human civilization. However much our modern positivism may resent this way of putting it, the essential truth of what he meant to convey, in this respect, stands out clearly enough.

Second, the motor of Marx's economic development was indeed not quite the colorless Saving of J. S. Mill: he linked it—or investment—to technological change in a manner that is not to be found in the latter's *Principles*. But all the same the motor is Saving, which with him is as promptly turned into investment as it is with Mill. This fact is hidden but not abolished by Marx's use of the term Accumulation and by his violent diatribes against the 'nursery tale' (*Kinderfibel*) that physical capital is created by saving. There are good reasons as well as bad ones for Marx's dislike of the latter term. In particular, capitalist fortunes do not typically arise from saving income dollars and piling them up neatly, but by the creation of sources of returns, the capitalized value of which then constitutes a 'fortune.' However, the implications of this he would not have liked any better than he did the picture of good and frugal boys who save till they find themselves rich. So it had to be Exploitation forever, so exclusively in fact as to endanger the explanatory value of his schema: for the social process as a whole, the essential point is in any case the capacity-creating use made of capitalists' gains—no matter whether or not they arise from exploitation and are invested again for the purpose of further exploitation—and this essential point, so a history of analysis has to notice, is fundamentally the same with Marx and Mill, however different the phraseologies were in which they conveyed it.

---

[5] In this and other respects, the case is similar to that of the doctrine of the essential harmony of class interests. On investigation, this doctrine turns out to be only partly tenable—but rather more so than does the doctrine of the essential antagonism of classes. But the latter has been preached with unsurpassable force and, moreover, renders the radical intellectual's ideology. The former has never been put forcefully or even convincingly. And it does not suit the book of the radical intellectual. So he who holds it is likely to be sneered at as a sort of Caspar Milquetoast, and this is quite as effective as, or more so than, serious argument would be. In the present case, there is something else however. No matter what the reason is, it is a fact that pessimistic views about a thing always seem to the public mind to be more 'profound' than optimistic ones.

[6] It was pointed out above that Marx took his picture of social reality from the radical ideology of his formative period.

CHAPTER 6

[General Economics: Pure Theory][1]

[1. AXIOMATICS. SENIOR'S FOUR POSTULATES] 575
  [(a) *The First Postulate*] 576
  [(b) *The Second Postulate: the Principle of Population*] 578
  [(c) *The Fourth Postulate: Diminishing Returns*] 584
2. VALUE 588
